The fate of the iodine in the thyroid was determined by Mann and Leblond in two groups of dogs: those given amounts of iodine comparable to the minute quantities present in the food of man and those receiving a dose of iodine comparable to that used in therapy. In physiologic conditions the iodide coming from the blood stream accumulates in the thyroid mainly as diiodotyrosine. This is the natural precursor of thyroxine. The results indicate that 155 per cent of the thyroxine contained in the thyroid is formed hourly. When excessive or therapeutic doses of iodine are administered, the iodine is incorporated in the gland probably as stored iodide. In relation to the large dose administered, the proportion which is transformed into diiodotyrosine is much smaller than in the small dose administration.

Dyspepsia in the Royal Navy—Wade states that 217 of the 1,003 consecutive cases of dyspepsia encountered at a large navy auxiliary hospital between October 1939 and October 1941 were in the active service of the Royal Navy and 786 were reserve and "hostilities only" personnel. The diagnosis in all was confirmed by roentgen examination or at operation. There is no evidence that wartime service in the Royal Navy has increased the incidence of dyspepsia. The expansion of the service and the inclusion of personnel from the prewar civilian population account for any apparent increase in incidence. An urgent need for organized clinical research into all aspects of the problem of dyspepsia of uncertain origin (so called gastritis) is revealed, in the series such dyspepsia was diagnosed in 24 per cent of the patients, 175 of whom had joined the service since the war began. Usually the history was long, only 12 per cent of the patients with duodenal ulcer and 20 per cent of those with duodenal dyspepsia dated their symptoms from the taking up of war service, 62 of 404 with duodenal ulcer and 17 of 148 with duodenal dyspepsia had symptoms for eleven to fifteen years. Of the 1,003 patients 56 per cent had clinical ulcers, in 47 per cent ulceration was proved roentgenologically (67 per cent gastric, 40 per cent duodenal and 0.5 per cent anastomotic). 15 per cent had duodenal dyspepsia and 24 per cent suffered from dyspepsia of uncertain origin. Patients with proved peptic ulceration should be invalided from the service unless circumstances permit adequate dietary control. In all, 329 of the 1,003 were invalided from the service. Overcooking reheating of meals, excess of canned and fried food and short mealtime are difficult factors to control on small ships. Many patients had taken alkaline powders regularly to control symptoms.

Passive Hyperemia for Chilblains—Herxheimer produced artificial hyperemia by Bier's method of applying a constricting rubber bandage at the middle of the humerus or femur of 24 persons suffering from chilblains. Most of the patients were

schoolboys, the treatment of 21 was completely successful in five to seven days. Swelling, pain and itching disappeared and small ulcers and cracks of the skin healed. The only remaining sign was redness of the skin, sometimes associated with thickening and wrinkling. In spite of this early success, treatment was continued for at least six weeks because if it was interrupted after a week or a fortnight the chilblains recurred at once but did not after the prolonged period of treatment. A Martin's bandage 2½ to 3 inches wide was used, but any other elastic bandage, even bandages made without rubber, will do. The color of the limb should deepen under its influence, but it should not become colder to the touch than it was before, and the feeling of pins and needles should not ensue. On the other hand, the constriction should be so firm that this sensation and coldness are only just avoided. A reliable sign of correct technique is that the big veins in the elbow protrude and that the arm is deep purple without being uncomfortable. In some cases swelling of the hand, a sign of too firm bandaging, is visible next morning, but this subsides in a few hours. The bandage may be left in position for twenty-two out of the twenty-four hours, but usually all night treatment is sufficient. The beneficial effect of this local venous congestion is not easily understood. It seems that the unimpeded arterial inflow forces blood through all potential blood spaces in the limb, including the capillary spaces dilated (and paralyzed) by cold, thus reopening the circulation through them.

Changes in Brain in Fatal Hypoglycemia—The neuropathologic changes in 6 fatal cases of hypoglycemia are described by Lawrence and his associates. The lesions were similar in all and differed only in intensity and the stage of the process. Widespread degeneration and necrosis of nerve cells were found, with corresponding microglial and macroglial proliferation, homogenizing and severe nerve cell changes were the predominating types of degeneration. The cerebral cortex, the caudate nucleus and the putamen were most affected, the cerebellum less so and the remaining centers of the brain stem were slightly involved. In 2 cases a widespread glial fibrosis of the cerebral and cerebellar white matter was a striking feature. The pathogenesis is discussed in relation to the biochemical alterations in hypoglycemia and in comparison with similar lesions in anoxia. The main cause is considered to be failure of the vital oxidative processes from lack of substrate dextrose, probably reinforced by subsequent vasomotor disturbances. The primary factor seems to be chemical and akin to anoxia.

*Wound Treatment with Chlorophyll Ointment F. Boehringer—p 850

Nystagmus as Recessive Sex Linked Characteristic—Kaser presents the genealogical table of a family with hereditary nystagmus The table includes six generations and 121 persons, of whom 13, or 10.7 per cent, had a pronounced nystagmus The pronounced nystagmus appeared only in men but was transmitted by women Thus it is a recessive sex linked defect In addition to the 13 persons with pronounced nystagmus 3 men and 3 women were discovered with a nystagmus elicited only on extreme rotation One man exhibited jerking of the head without accompanying nystagmus Nystagmus on extreme rotation and jerking of the head in supposedly healthy members of the family are interpreted as manifestations of a familial defect Three persons presented nystagmus and head jerking in combination The family likewise included members with amblyopia myopia, hypermetropia and astigmatism, but also many with normal eyes

Wound Treatment with Chlorophyll Ointment—At Boehringer's clinic in Bern, it is the rule to test new remedies for wounds only when control experiments can be made, as on patients with several wounds or a single wound of such extent as to permit one half to be treated with the new preparation and the other with a control substance Under such conditions the differences in results with the use of expensive ointments and isotonic solution of sodium chloride were negligible In some instances isotonic solution of sodium chloride actually appeared superior Chlorophyll ointment has been tested at the Bern clinic for some time Of the 8 cases in which chlorophyll ointment was used and in which other salves were employed for control purposes 7 exhibited better granulation under chlorophyll ointment than under that of other ointments Epithelial growth was the same under chlorophyll and control ointments One case failed to respond to ointment treatment of any kind In 5 additional cases treatment with chlorophyll ointment produced a favorable change in chronic torpid wounds Chlorophyll ointment has proved particularly valuable in torpid wounds and in wounds with extensive and deep tissue defects

Universal Blood Donors T. Escayudillo—p 56

Osteoarticular Tuberculosis in Infancy R. F. Tijero—p 65

Cholesteremia in Healthy Infants and in Dystrophy and Toxicosis—According to Lloa Ricketts the biologic role of cholesterol in immunity, in erythrocytic resistance, in cellular absorption and as an antitoxic factor has acquired great importance in the light of recent studies There is no record of the importance of cholesterol in dystrophy and toxicosis The author investigated blood cholesterol by means of an electric photocolormeter in young children with these two disorders His studies were made on 57 infants and children 15 were healthy 22 had dystrophy and 20 had toxicosis The quantity of cholesterol in healthy children up to 2 years of age averaged 171 mg per hundred cubic centimeters and varied between 140 and 200 mg There exists a close parallelism between the weight and the cholesterol content of the blood In obese children the blood cholesterol values may reach 250 mg per hundred cubic centimeters Dystrophy is always accompanied by hypcholesteremia which is the more pronounced the more grave the dystrophy The lowest values, 53 correspond to athrepsia The blood cholesterol content of children with toxicosis is likewise inferior to the normal average, it decreases in direct ratio with the loss of water One of the factors responsible for infection, anemia, disturbance in water exchange and the toxic state which are observed in dystrophy and toxicosis is hypcholesteremia The determination of the quantity of blood cholesterol in dystrophy and toxicosis is of prognostic importance The prognosis is unfavorable when values of less than 100 mg per hundred cubic centimeters are present

Book Notices

Therapeutics of Infancy and Childhood Edited by Harry R. Litchfield, M.D. F.A.C.P. Attending Pediatrician, Beth El Hospital, Brooklyn, and Leon H. Dembo, M.D. Visiting Pediatrician, St. Luke's and St. Anne's Hospitals, Cleveland, Ohio. [With] 117 Contributors. In four volumes and de k. Index. Fabrikoid. Price \$32. Pp. 816, 1001, 1816, 2001, 2745. '001 3831 1 203 with illustrations. Philadelphia: F. A. Davis Company, 1942.

One hundred and seventeen contributors have combined to prepare this work which includes four volumes and a desk index. Forty years have passed since the publication of Jacobus' comprehensive book on the therapy of infancy and childhood. The advances that have been made since that time, particularly in relationship to specific therapy, biologic and glandular therapy, and new methods of treatment for diseases formerly considered incurable would alone warrant a work of such great scope as is the system here reviewed. Moreover, the mental aspects of child care are in themselves so important and have been so exhaustively investigated that they too would well warrant a systematic discussion.

Recognition of the importance of the mental aspect is revealed in the first chapter, which is concerned with the psychological care of the sick child, followed by another on the art of treatment. Then come considerations of legislation affecting therapy, medical aid until the doctor comes, and a consideration of various materials and techniques used in treatment. The remainder of the first volume is devoted to asphyxia neonatorum, anomalies, nutrition, disorders of the skin and the acute infectious diseases.

Subsequent volumes cover rheumatic fever, the diseases of various regions of the body including the circulation, diseases of metabolism and of the nervous system, and, in the final volume, tropical diseases, radiation therapy, diseases of the skin and surgery. A detailed index volume completes the work.

The selection of authors has been excellent, embracing most of the well-known pediatric clinics of the United States. The type selected is an exceedingly large type with plenty of white space, indicating no doubt the development and planning of this work well in advance of the restrictions now placed on paper and printing by the exigencies of the war. The modern character of the work is shown in the special chapter on blood plasma, which is discussed in great detail with numerous illustrations. Indeed, the many colored illustrations in this work are an indication of its comprehensive and elaborate approach to this subject.

In his chapter on whooping cough, Dr. Sauer has brought down to date the present point of view regarding that disease. Each of the chapters is accompanied by a bibliography, unfortunately limited to names of authors and periodical references without in any instance providing titles of the articles concerned. For the young man about to undertake a pediatric practice, a work of this type is exceedingly valuable since it will bring him promptly into touch with the latest points of view regarding any of the problems which may come before him. As might be expected in such subjects as the treatment of burns and in much of the surgery concerned, time was too short to permit some of the changing points of view brought about by the experience of the war. It is rather strange to find appended to the volume, almost as an afterthought, a special chapter on hypertension—a subject which, incidentally, is not of primary importance as a condition affecting the child.

The Hormones in Human Reproduction By George W. Corner. Cloth. Price \$2.75. Pp. 265 with 56 illustrations. Princeton, New Jersey: Princeton University Press; London: Oxford University Press, 1942.

The author presents a comprehensive story of reproduction, beginning with the simple processes exhibited in the lower animals and ending with the complicated processes in the higher apes and the human being. The physiology of menstruation, ovulation, fertilization and early implantation of the fertilized ovum are clearly described. The changes in the uterus and the endocrine glands as a result of pregnancy are discussed. Most of the chapters are devoted to the glands and the hormones which control reproduction. The discovery of the ovarian hormones, their isolation, their chemistry and their physiologic role are described by presenting many key experiments by numerous

investigators. The story of progesterone, with which the author was closely identified, is particularly interesting.

This small monograph is the result of the Vanuxem Lectures which the author delivered at Princeton in February, 1942. These lectures with many additions have been embodied in one of the most delightful books that has come to the attention of the reviewer in many years. All the scientific data have been carefully evaluated by one of the foremost scholars in the field of reproduction and yet they are presented in such a simple, interesting manner that any college student can follow the discussion with ease. The numerous illustrations, many of which are simple, add greatly to the clarity and interest of the text. Pertinent quotations from the literature introduce each chapter. This small book should be read by every student of biology as well as by the ever increasing number of men and women who are intrigued by the miracle of reproduction.

Just for Two: A Handbook of Cookery for the Small Household By Lily Maxworth Wallace. Cloth. Price \$2. 1 p. 311. New York: M. Barrows & Company, Inc., 1942.

Home Canning for Victory: Also Preserving, Pickling and Dehydrating (compiled and edited by Anne Pierce). Cloth. Price \$1.25. 1 p. 106 with 3 illustrations. New York: M. Barrows & Company, Inc., 1942.

Diet Without Despair By Marion White. Cloth. Price \$1.00. Pp. 128. New York: M. S. Mill Co., Inc., 1943.

Sweets Without Sugar By Marion White. Sixth printing. Cloth. Price \$1.25. 1 p. 125. New York: M. S. Mill Co., Inc., 1943.

The Food You Eat: A Practical Guide to Home Nutrition By Samuel and Violetta Cassione. Cloth. Price \$2.25. Pp. 177 with 15 illustrations. Norman: University of Oklahoma Press, 1943.

If ever anybody needs a cookbook, it is likely to be the new bride who is trying to plan meals for herself and her husband. Even her mother will sometimes have trouble translating the quantities of a large household into something suitable for two people. There are many dishes that are easy to make and are economical when prepared for a large family but difficult if not impossible to prepare in small amounts. "Just for Two" is designed particularly for meeting this need. It begins with a statement on the essentials of a well-balanced diet, indicates the need for a satisfactory breakfast and lunch, particularly for those who are working, and then provides unnumbered recipes worked out in chapters according to the class of foods concerned. Sections on how to market and how to plan daily meals for variety, flavor, nutrition value and economy are especially worth while.

The experience of the author of "Home Canning for Victory" in conducting the section of the *New York Herald Tribune* concerned with home economics is warrant of her ability to consider the subject which she covers in this book. All of the problems related to home canning are modified at this time by the ability to secure materials to be canned and packages in which to do the packing. Dehydration is for most people a new process. Miss Pierce considers home canning, preserving, making pickles and relishes and dehydration of food. A number of articles in the appendix are especially practical. Here are time tables for all of the processes involved and a discussion of utensils and of the sugar situation. The book is excellently printed.

Dieting demands, most of all, will power and full information regarding the number of calories in an ordinary serving of most foods. "Diet Without Despair" provides the charts and in addition a good many recipes for items that are low in calories. There is even a section devoted to cakes and pies, with the warning that the butter and the cream and sugar in the frosting are the chief items to be avoided. Here is information on how to make a low-calorie sponge cake and also menus for such special occasions as bridge luncheons, afternoon teas, midnight snacks and drugstore luncheons for the business girl. By its emphasis on mathematics this book fills a special need.

Miss White has also made available a book on "Sweets Without Sugar" and, for that matter, without saccharin. She substitutes, however, honey, molasses, corn syrup and maple syrup, with a recognition of their content. Unfortunately, some of the statements regarding the food value of the substitutes are slightly exaggerated, since they do not take account of the amounts of these substances necessary to give equal sweetening value.

The university presses are making many valuable contributions to American publications. "The Food You Eat" from the University of Oklahoma is a modern, up-to-date, simple presentation of food problems based on a knowledge of the physiology of digestion, new information regarding the vitamins and a practical experience with menus. The book is supplemented with an outline on practical nutrition and a good index.

Abdominal and Genito Urinary Injuries. Prepared under the Auspices of the Committee on Surgery of the Division of Medical Sciences of the National Research Council. **Abdominal Injuries.** Prepared by Ambrose H. Storck. Everts A. Graham, Chairman. **Genito Urinary Injuries.** Prepared and edited by the Subcommittee on Urology of the Committee on Surgery. Herman L. Kretschmer, Chairman. Volume III. Military Surgical Manuals. Cloth. Price \$3. Pp. 243 with 79 illustrations. Philadelphia & London: W. B. Saunders Company, 1942.

This is the third volume of a series of six manuals prepared under the auspices of the Committee on Surgery of the National Research Council as concise presentations of fundamental knowledge in the various fields of surgical specialization in relation to military surgery. They were originated, planned and largely written before Pearl Harbor, being thus a monument to the foresight of the surgical profession but perhaps suffering slightly from their prewar origins. The set of war manuals was designed to crystallize in short, practical form present day knowledge of the basic principles of surgery in all fields of specialization, applied to the problems of trauma produced by enemy action. The volume under review is well done and will probably suffer little from new observations based on experience on the firing lines of today.

Part I, on abdominal injuries, comprises eleven chapters with many pertinent and well executed drawings by Miss Vera Morel that illuminate and clarify the text. The chapters deal in an orderly manner with all phases of the management of abdominal injuries from their reception, study and diagnosis to general care and preoperative preparation, the selection for operation, the anesthetic, the operative procedure, wounds of special organs, postoperative treatment, complications and a final evolution of results, mortality and statistics. The whole is covered by an emphasis on the patient rather than on one particular injury, with excellent balance and an emphasis on fundamentals that will not change although they may be garnished by newer experience in the field. There is at this time no more pithy presentation of the basic principles of the treatment of abdominal trauma than is here proffered, and the author is to be heartily commended for an admirable summary of postwar experience, combined with modern scientific advances.

Part II consists of six chapters on genitourinary injuries, prepared and edited by a distinguished group of urologists, and is comprehensive, authoritative and complete. Diagnostic methods are explained in great detail and in a practical way. The discussion of renal and ureteral injuries is commendable for its completeness and soundness. The treatment of crushing injury and renal failure is both timely and apropos. However, in light of recent research it is becoming evident that, in cases reported in the British literature, renal failure has not resulted from toxic degenerative products of traumatized muscle, as has been thought by the foreign observers, but rather from intravenous saline solution administered to these patients for treatment of their shock. The complete discussion of the care of the neurogenic bladder is particularly praiseworthy and should be read and reread by all physicians who expect to treat war casualties. The principles enunciated are sound and the procedures described are essential to good practice in this difficult group of cases.

This volume can be heartily recommended to those who will have opportunity for treating patients injured by missiles of war and accidents of civil life.

The Standard of Living in 1860. American Consumption Levels on the Eve of the Civil War. By Edgar W. Martin. Cloth. Price \$4.50. Pp. 451. Chicago: The University of Chicago Press. London: The Cambridge University Press, 1942.

A distinguished committee which studied economic changes in the United States in 1923 pointed out that the most significant factor in the changes that had occurred in the previous quarter century had been the increasing expansion of human desires and wants. In no other field perhaps has this expansion been more significant than in the field of medicine and public health. The author discusses the conditions that pre-

vailed in 1860 in diets, housing, clothing, transportation, education and leisure. One chapter is devoted to medical care and the public health. Characteristic of the 50's were high death rates and low life expectancy. The first disease microbe was identified in 1863, but anesthetics had come in in 1844. Quacks and frauds preyed on the ignorant masses. Phrenologists and spiritualists claimed special abilities, hydropathy and homeopathy were in their heyday. The legal requirements for practice were not exacting. There were only faint indications of trends toward specialization. At that time there were only 5,600 dentists in the country, or about 18 for every 100,000 persons. There were only 8,000 nurses, or about 26 for every 100,000 persons. The first hospital training school for nurses was opened in 1873. As late as 1890 there were less than 500 graduate nurses in the United States. There were wide differences between the quality of medical practice in different parts of the country. In many plantations physicians were employed on a yearly salary to take care of slaves. The average annual income for country doctors in Alabama was \$1,000, \$2,000 for the city practitioner. Medicine was then just on the threshold of becoming a science. In 1873 there were only 149 hospitals in the country. In 1923 there were 6,762. In the Massachusetts General Hospital at that time there was no attempt to classify or segregate patients. There was no public health nursing until 1877. Only a few cities had boards of health in 1860. The first state board of health was established in 1869. From a recapitulation of the situation then prevailing and a comparison with the advancements of today one must derive great encouragement.

Diseases of Women. By Ten Teachers under the direction of Clifford White, M.D., B.S., F.R.C.P. Edited by Sir Comyns Berkeley Clifford White and Frank Cook. Seventh edition. Cloth. Price \$6. Pp. 435 with 168 illustrations. Baltimore: William Wood & Company, 1942.

It is a remarkable achievement to revise a book under present conditions existing in Great Britain. That this has been successfully accomplished by nine contributors is even more creditable. The popularity of this gynecologic textbook is evidenced by the fact that this is the seventh revision. The gynecologic subjects are covered in a brief and concise manner, including the etiology, symptoms, diagnosis and treatment. Controversial data have been entirely eliminated. All the contributors have read and constructively criticized the entire book, so that the conclusions represent a good cross section of gynecologic thought and practice in the British Isles. There is little to which one can take exception. The Wertheim operation for carcinoma of the cervix has been replaced by irradiation in most clinics in the United States. American gynecologists do not favor the transplantation of ovarian fragments in the event that it is necessary to remove both ovaries in young women. A few operative procedures are presented rather sketchily in the last chapter. The descriptions may be sufficient for one who has had operative experience but they would not suffice for the novice. The book is an excellent outline of gynecologic thought and practice.

Silent Enemies. The Story of the Diseases of War and Their Control. By Justina Hill. Cloth. Price \$2.50. Pp. 266. New York: C. P. Putnam's Sons, 1942.

The success of Dr. Hill's contribution "Germs and the Man" has led her to reflect for the public interest some of those conditions caused by bacteria which are particularly a problem of war. Thus she has sections on the tropical diseases, the plagues, wounds and burns, the respiratory diseases, filth, venereal diseases and the viruses. The final chapter indicates the tremendous scope of the postwar problem, which involves the freeing of the world from the menace of all the various forms of contagion likely to become widespread by the movement of great bodies of troops. The health problems of relief and reconstruction abroad, including the care of refugees, are likely to be almost as difficult a task as the winning of the war itself. Badly needed, says Dr. Hill, is a chemical coup for the viruses equivalent to what the sulfonamides have done for the bacteria. Needed also are drugs of equal potency against tuberculosis and syphilis. She indicates the need for improved research in many fields. Altogether, the book is one of the most pleasantly written and informative available to the general reader.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

HYPERHIDROSIS OF FEET

To the Editor—A man aged 27, a butcher, shows no physical abnormalities but he presents an unusual and to him a distressing phenomenon. In summer his body perspires profusely yet his feet are dry in the winter the reverse is true, his body being dry but his feet constantly wet with perspiration even though he bores his feet daily wears thin socks and shoes and does the same amount of work the year round. Please advise me regarding the probable cause of this condition and what can be done for it.
M D New York

ANSWER—The general sweating of the body in the summer is not remarkable; some people naturally sweating more than others. This may be increased by such diverse factors as obesity, hyperthyroidism, organic changes in the central nervous system and exhausting illness. The hyperhidrosis of the soles would not be expected to manifest itself particularly in summer, because the sweating of the palms and soles is somewhat independent of temperature. At these sites accentuation is speeded up by emotional stress. Here too the insensible perspiration is greater than at other sites, except perhaps at the axillae. This insensible perspiration consists of two elements, namely the smaller amount as a physical discharge of water through the epidermis and the larger perpetual secretion of sweat. This not inconsiderable amount of liquid forming on the palms and soles regardless of temperature has to be volatilized. There might be a less ready evaporation during winter, especially in one whose skin is cool. At any rate persons with a climatic type of circulation tend to have hyperhidrosis of the palms and soles. This is commonly expressed as the cold, clammy hand or foot. There are no data at hand to show whether such extremities actually sweat more or volatilize less readily what they do secrete by reason of lower surface temperatures. Other causes for hyperhidrosis of the soles may be flat feet and impaired circulation. It might be worth while inquiring into possibilities of undue stress or diet. It is known that certain articles of food and some drugs are capable of inducing excessive sweating in some people and especially at localized sites. Among such foods should be mentioned chocolate, tomatoes, cheese, pickles and onions.

If none of the elements suggested can be found in the background as contributing agents in this case, certain measures may be instituted to give some relief. Dehydration therapy with curtailment of the fluid intake and the administration of atropin or belladonna. For the feet, dusting powder of talcum or mixed with boric acid 5 to 10 per cent, salicylic acid 1 to 3 per cent and formaldehyde 1 to 3 per cent (formaldehyde is capable of producing a dermatitis through sensitization). Aqueous solutions of the following are somewhat easier to use and more effective: boric acid, salicylic acid or formaldehyde in 3 per cent concentration; aluminum chloride 10 to 25 per cent and sodium hexametaphosphate 1 to 5 per cent. They may be applied morning and evening and then less often when the amount of sweating is reduced. The use of x-rays for the control of hyperhidrosis is a method preferred by the patient. There is a difference of opinion regarding the advisability of its use. Conservative opinion holds that sufficient doses to produce atrophy are necessary to achieve the desired reduction in sweating. This in turn leads to persistent dryness of the palms and disagreeable sensations often worse than the original hyperhidrosis.

AMPHETAMINE FOR OBESITY

To the Editor—Kindly give me information as to the use of amphetamine (benzedrine) sulfate and dextroamphetamine in the treatment of obesity.
M D California

ANSWER—Amphetamine sulfate is a sympathomimetic drug which stimulates the higher cerebral centers, especially the cortex. The dextro-rotatory form is said to be two to four times more active than the levo form or the mixture. Among its many actions it may cause anorexia with such associated complaints as nausea, belching, flatulence, abdominal cramps and a disturbance in bowel habits. Since anorexia follows its use, amphetamine has been employed in the treatment of obesity. It is maintained by Ersner that when a patient loses his appetite he is more likely to follow diet. With this statement there would be no disagreement.

The depression of the appetite would seem to be the chief action of amphetamine in the treatment of obesity, since the effect on the basal metabolic rate is neither constant nor significant. Altschule and Iglauer found an increase in the basal metabolic rate in only 2 of 12 normal subjects following the use of the drug, and in these they attributed the increase to restlessness. Dill, Johnson and Daly reported a definite calorogenic action following intramuscular injection in man.

The impression is gained that the loss of appetite, the increased activity and the restlessness of patients under the influence of amphetamine are sufficient to account for the weight loss which often follows its continuous use. This drug should be used only under the careful supervision of a physician and when disagreeable side effects appear it should be discontinued.

EOSINOPHILIA AND PARASITIC INFECTION

To the Editor—I have recently had 2 patients with eosinophilia. The first, a man aged 61, a plumber, gave a history of becoming violently nauseated soon after eating a meal about Aug. 1, 1942. He does not remember what he ate. He had no diarrhea. About two weeks after this he began to tingle and itch all over his body from head to toes and this tingling has continued to the present time. About the time the tingling began he had a severe itching spell and a red blotchy rash across the abdomen. He has lost 20 pounds (9 Kg.). He has not had further vomiting or muscle or joint pains. The physical examination was essentially negative. His blood picture on Dec. 4, 1942, was as follows: hemoglobin 90 per cent, erythrocytes 5,800,000, leukocytes 11,500, polymorphonuclears 29 per cent, eosinophils 53 per cent, lymphocytes 18 per cent. The sedimentation rate was 12 mm. in one hour. The serum Kahn and Kline reactions were negative. A biopsy from the deltoid muscle 5 mm. in diameter contained no trichinae. Examination of warm stools after a saline purge showed a few ova both fertilized and unfertilized of *Ascaris lumbricoides*. In the third stool passed were numerous parasites that fit the description of *Strongyloides stercoralis*, some of them alive and most containing ova. The other patient was a housewife aged 24. On Nov. 30, 1942, she complained of aching over the whole body but especially in the arms and of a severe headache. She had been aching for a week. The pain began in her right shoulder. Any movement starts the pain in the arm. There is no history of any gastrointestinal disturbance except cramping immediately after putting food in the stomach. There was no rash. Her temperature varied from 99.8 to 100.5 F. She gave a history of liking her meat not too well done and also of usually taking a bite of raw lean meat when sleighing bacon. On Dec. 4, 1942, her blood picture was as follows: hemoglobin 75 per cent, erythrocytes 5,100,000, leukocytes 10,500, polymorphonuclears 59 per cent, eosinophils 21 per cent, lymphocytes 20 per cent. The sedimentation rate was 29 mm. in one hour. The serum Kahn and Kline reactions were negative. Muscle biopsy has been refused up to the present time. An examination of stools for parasites was done and no ova were found but one parasitic worm was found containing a row of embryo worms. The embryos were partially uncoiled so that they formed a line of identical S's lying sideways. The head and tail of the adult worm were not seen. Neither of these patients has lived outside the state of Ohio. They have had no contact with each other. Intracutaneous tests with trichinella extract 1:10,000 were negative in the case of the man and a doubtful positive in the case of the woman. Could the first patient's symptoms be due to infestation with *Strongyloides*? What is the probable identity of the parasite found in the second patient?

M D Ohio

ANSWER—In connection with the first case it is improbable that the symptoms and eosinophilia were due to *Strongyloides*. Only in extremely heavy infections is such a high eosinophilia encountered, and larvae would have been found in large numbers in every stool specimen. It is doubtful that the parasites found were *Strongyloides* because only larval forms would be found in fluid stools and larvae do not contain ova. Parthenogenic female *strongyloides* would not be evacuated ordinarily by a saline purge. It is suggested that this patient's stools be examined again by a competent parasitologist. The eosinophilia might have been caused by sensitivity to some foreign protein other than an animal parasite. If the eosinophilia still persists, another cutaneous test for *Trichinella* might be performed although the symptoms were not typical of that infection.

In the second case the description of the presence of an adult worm containing embryos is not typical of any parasite commonly infecting man. It might have been a free living worm swallowed with food or drink. The description sounds more like an artefact. In this case again a reexamination of the stools by a competent parasitologist is recommended.

TECHNICS OF ERYTHROCYTE SEDIMENTATION TESTS

To the Editor—I should like to ask regarding the present status of the normal range for the erythrocyte sedimentation index. During my internship and residency I used the Linzenmeier technic wherein the time was recorded in which an 18 mm fall occurred. This was two hours for women and slightly less for men corresponding to 9 mm an hour. This was frequently compared to the standard Wintrobe hematocrit tube. Yet in The Journal March 7 1942 page 779 the authors consider as an increased sedimentation rate one exceeding 20 mm in one hour. My query is: What is the normal index or rate for the various technics? Has any attempt at standardization of technics been made? How should the index be stated preferably as time or as millimeters? Also it has been stated that pertussis allergy and liver disease prolong the sedimentation time. Is it known in what way this occurs?

R G Lehman Lieutenant, M C, U S N R

ANSWER—There is no one standard method for performing the sedimentation rate, and the variety of technics and methods for expressing results continue to cause confusion. The Westergren method is probably used more than any other. In general the sedimentation rate of erythrocytes usually serves as a rough

volume of venous blood, the mixture drawn into the Westergren tube. Other investigators have modified the proportion of sodium citrate solution used for the Westergren method or have substituted potassium oxalate as the anticoagulant. These modifications do not improve Westergren's method but add further confusion by changing the values for the normal and abnormal range of sedimentation rates. Change in the anticoagulant to a small volume potassium oxalate, for example, alters the characteristics of the settling velocity, increases the rate for normal subjects and increases the effect of anemia, which is minimal in the original Westergren method. The unmodified Westergren method performed with one reading at the end of one hour and without correction for anemia is the best simple method available for clinical purposes.

Preferably the sedimentation rate should be expressed as the number of millimeters of settling per hour or per minute as observed during the period of constant settling velocity rather than the less convenient method of Linzenmeier, namely the

Comparison of Five Commonly Used Sedimentation Methods

Sedimentation	Rourke-Ernstene	Wintrobe-Landsberg	Westergren	Linzenmeier	Cutler
Tube length	120 mm	120 mm	300 mm	65 mm	70 mm
Internal diameter	4.0 mm	2.5 mm	2.5 mm	5.0 mm	5.0 mm
Graduations	0-100 mm	0-100 mm	0-200 mm	0-18 mm	0-50 mm
Height of blood column	100 mm	100 mm	200 mm	50 mm	50 mm
Anticoagulant	Heparin 15 per cent Dry oxalate mixture * Potassium oxalate †	Dry oxalate mixture *	Sodium citrate 3.8 per cent	Sodium citrate 5 per cent	Sodium citrate 3 per cent
Amount	0.013 cc heparin in 3 cc blood. For oxalates see notes.	See note	0.2 cc in 10 cc mixture	0.2 cc in 10 cc mixture	0.1 cc in 10 cc mixture
Concentration (mg per 100 cc mixture)	60 heparin 200 oxalates	200	760	1,000	800
Dilution of blood (per cent)	0.4 heparin 0.0 dry oxalate mixture 1.0 potassium oxalate	0	20	20	10
Method of timing	Slope of period of constant fall	Distance settled in 1 hour	Distance settled in 1 hour	Time to settle to 18 mm	Graph of curve and distance settled in 1 hour
Sedimentation rate units	Millimeters per minute	Millimeters	Millimeters	Minutes	Slope of curve and millimeters
Correction for erythrocyte concentration	Required	Required	Seldom used	None	None
Normal range	0.0-0.40 mm per min	0.9 mm men 0.15 mm women	1.3 mm men 4.7 mm women	200-600 min	Horizontal line and 2.8 mm men 2.10 mm women
Abnormal range					
Slight	0.4-0.6 mm per min	10-20 mm men 20-25 mm women	8-15 mm	100-900 min	Diagonal line
Moderate	0.6-1.0 mm per min	20-30 mm	15-40 mm	60-100 min	Diagonal curve
Extreme	2.0-2.5 mm per min	35-50 mm	80-110 mm	15-30 min	Vertical curve

For discussion of anticoagulants see Ham T H and Curtis F O. *Medicine* 17: 447 (Dec) 1938.

* Dry oxalate mixture. The solution is made by dissolving 3 Gm of crystalline ammonium oxalate and 2 Gm of crystalline potassium oxalate in distilled water with the aid of heat making the final volume to 100 cc. This gives an oxalate mixture concentration of 5 Gm per hundred cubic centimeters. The concentration employed for blood is 200 mg of oxalate mixture per hundred cubic centimeters of blood. Accordingly 0.013 cc of the solution is pipetted into a tube or bottle for each 5 cc of blood to be drawn. The anticoagulant is then dried (to prevent dilution of blood) by heating in an oven at 100°C for one hour or by desiccation at room temperature for several days. This anticoagulant has the advantage that it causes no change in erythrocyte size and no change in the sedimentation rate.

† Potassium oxalate. The solution is made by dissolving 20 Gm of crystalline potassium oxalate in distilled water with the aid of heat making the volume up to 100 cc. Concentration employed is 200 mg per hundred cubic centimeters of blood. Accordingly 0.013 cc of solution is pipetted accurately for each 5 cc of blood. This anticoagulant is not dried. It produces somewhat variable shrinkage of the erythrocytes which can be corrected approximately by multiplying the erythrocyte volume (hematocrit reading) by the factor 108. This anticoagulant does not influence the sedimentation rate.

index of the concentration of plasma fibrinogen. The sedimentation rate of erythrocytes fails, however, as an index of plasma fibrinogen when there are abnormally elevated levels of serum globulins or of lipids and when there is advanced microcytic or macrocytic change in the red blood cells. The closest correlation between the sedimentation rate and the concentration of plasma fibrinogen has been obtained by use of the Rourke-Ernstene method and the Westergren method. Poorer correlation has been obtained by the methods of Linzenmeier, Cutler and Wintrobe-Landsberg. Each of these five methods, however, has proved useful clinically. The Rourke-Ernstene method is the most reliable but also the most time consuming and complex.

The Westergren technic is a simplified procedure which has been widely used and can be recommended since a single reading in millimeters taken at the end of one hour, uncorrected for anemia, has a high degree of correlation with concentration of plasma fibrinogen. This is true for the Westergren method performed as described by the author, employing 20 per cent by volume of 3.8 Gm of sodium citrate solution per hundred cubic centimeters as an anticoagulant, mixed with 80 per cent by

observation of the time in minutes required to settle 18 mm. A quantitative comparison of the five commonly used sedimentation methods has been reported by Ham and Curtis (*Medicine* 17: 413 and 447 [Dec] 1938) and by Hambleton and Christianson (*Am J M Sc* 198: 177 [Aug] 1939). Ham and Curtis have also discussed the relation of plasma proteins, especially plasma fibrinogen and serum globulins, to the sedimentation rate. A table of normal and abnormal sedimentation rates is submitted here.

It has been reported that the sedimentation rate is prolonged in allergic states, certain virus infections and certain cases of brucella infection. This indicates that the concentrations of plasma fibrinogen and of serum globulins are not elevated in these diseases. In overwhelming liver disease, however, the sedimentation rate may decrease from an abnormally elevated level to normal, coincident with a decrease in the plasma fibrinogen from above normal to below normal, with resulting fibrinogenopenia. This is a sign of liver failure which is encountered rarely (Ham and Curtis, p 413). A normal sedimentation rate or a so-called prolonged rate therefore is indirect evidence that

the plasma and serum globulins are not elevated above normal concentrations, but a normal sedimentation rate is not a reliable index for abnormally decreased concentrations of these globulins

SULFONE COMPOUNDS FOR PULMONARY TUBERCULOSIS

To the Editor—Will you please send me information on the treatment of pulmonary tuberculosis with the sulfone drugs or any other effective drug therapy? Is there enough backing for a trial of sulfone compounds in a fairly severe case of tuberculosis with considerable loss of weight?

L E Blachman M D, Cleveland Heights, Ohio

ANSWER—Feldman, Hinshaw and Moses were the first to employ in experimental tuberculosis a group of compounds known as sulfones. The nucleus of this group is 4,4'-diaminodiphenylsulfone. This parent compound has been found effective in controlling tuberculosis in animals, but, unfortunately, it is highly toxic. Therefore, various derivatives have been produced. Feldman and Hinshaw have employed not only the parent compound but ten derivatives in the treatment of experimental tuberculosis. Among these preparations five were found to have no significant effect, while the remaining six exerted varying good effects. The three which were found to be superior to all others are the parent compound and two derivatives, sodium p,p'-diaminodiphenylsulfone-N,N'-dixetose sulfonate (promin) and disodium formaldehyde sulfoxylate diaminodiphenylsulfone. The first of this group employed in experimental tuberculosis by Feldman and Hinshaw was the derivative commonly known as promin. They observed that, when this drug was administered a few days before animals were inoculated with tubercle bacilli, the expected course of the disease in these animals was materially altered; indeed, most of them were little affected by the disease. Animals were then infected with tubercle bacilli after which the administration of the drug was begun at different periods. Indeed, in some animals treatment was not begun until six weeks after the usual lethal dose of tubercle bacilli had been administered. At the end of six months all of the control animals, that is, those which had been infected and were not treated with promin, were dead. Autopsy revealed the presence of severe widespread tuberculous lesions whereas in 57 per cent of animals treated with promin it was impossible to find lesions in the liver, spleen or lungs. Moreover, those animals which were not treated until six weeks after they were infected fared as well as those treated earlier. The next experiment consisted in infecting guinea pigs with tubercle bacilli later performing laparotomies in order to visualize the lesions and actually take specimens from the livers for microscopic examination. About this time treatment with promin was instituted. When all the untreated control animals in this study had died from tuberculosis, 81 per cent of those treated with promin were still alive. Necropsies on these animals revealed that not only had the disease failed to progress after the administration of promin but the lesions had receded and resolved. This is the first time in the history of tuberculosis therapy that tuberculosis in animals has been completely controlled by a drug.

Hinshaw, Pfuetze and Feldman have administered promin to 106 tuberculous patients. Thirty-six of these received what was regarded as an adequate trial of therapy. The most favorable effects were observed on exudative pulmonary lesions of recent origin without extensive destruction of tissue and without definite fibrosis. All such lesions showed evidence of improvement within two months and were nearly or completely resolved within four to six months. They emphasized the fact, however, that many such lesions tend to resolve spontaneously and that their series of cases is not large enough to justify the conclusion that promin was responsible for the observed improvement in the treated cases. Closure of one or more cavities was observed in 10 of 26 adequately treated patients with cavities, and tubercle bacilli apparently disappeared from the sputum in 14 of 36 cases (39 per cent). The sedimentation rate was definitely decreased in 70 per cent of all cases with elevated rate. Among 18 febrile patients 10 showed significant reduction in temperature. In 1 patient a new progressive lesion developed in the course of the treatment. Four patients died 3 of whom were in the terminal stage before treatment was instituted. Six patients with tuberculous meningitis 2 of whom had treatment instituted in an early phase of the disease died. No noticeable effects were observed among 4 patients suffering from renal tuberculosis, but observations were incomplete in these instances.

The authors report that promin is potentially toxic when given in large doses, therefore the dose must be carefully regulated to avoid serious destruction of blood. Headache, restlessness, anorexia and malaise are the chief symptoms from which patients have complained. The authors are of the opinion that the results to date justify further clinical trial of promin and other drugs of the sulfone series, particularly among patients who have fresh exudative lesions. Under the direction of these workers a large number of patients are now being treated. Since the entire subject is in an experimental stage and since the drugs now in use are sufficiently toxic to result in serious harm to the patient, it seems best to refrain from prescribing these drugs until such time as their efficacy can be more definitely established and their dosage so standardized as to make their administration safe. No drugs of this series are available commercially at the present time.

Of all the other drugs that have been administered throughout the centuries, not one has been found efficacious in the treatment of tuberculosis in animals or man.

"CANNED HEAT" FOR EMERGENCY USE

To the Editor—Would you kindly inform me as to whether there is available a formula for a preparation of a substance such as the commercial 'Sterno' for use in heat sterilization in the event of a situation in which gas and electricity should be unavailable?

Shepard Shapiro M D New York

ANSWER—Commercial preparations termed "canned heat" are jellies commonly containing denatured alcohol as a source of heat. A suitable formula, according to the Chemical Formulae by Bennett, volume I 1933-1934, is denatured alcohol (methyl alcohol may be used) 1 000 cc., soap chips (well dried) 28 30 Gm., and shellac (dry flakes) 2 Gm. Heat the alcohol to 140 F (Caution: Danger of fire), add soap chips and shellac, until the solids are completely dissolved, pour into suitable metal capped containers and allow to cool.

ROENTGEN THERAPY FOR RECURRENT HYPERTHYROIDISM

To the Editor—The reply to a query on recurrent hyperthyroidism published in *The Journal* Dec 12 1942 page 1262, surprised me in that the writer appears to feel that thyrotoxicosis is mainly a surgical problem. There is at present a useful nonsurgical treatment of diffuse thyroid enlargement associated with thyrotoxicosis which is the application of radium used as a collar over the neck by the method described in 1913 by Dr Solomon Ginsberg. The consultant also stated in his reply that the skin may be burned which is a misstatement that has been printed in every textbook on thyroid disease by those who write about it but who have had no experience with radiotherapy. I can conservatively state that at least 80 per cent of the diffuse swellings of the thyroid gland associated with thyrotoxicosis can be cured in this way. I am so enthusiastic about this form of treatment that I hold it comparable to the action of sulfonamide drugs in acute bacterial infections.

WOMEN IN INDUSTRY

PRELIMINARY REPORT OF THE COMMITTEE ON THE
HEALTH OF WOMEN IN INDUSTRY OF
THE SECTION ON OBSTETRICS
AND GYNECOLOGY

RECOMMENDATION TO THE COUNCIL ON
INDUSTRIAL HEALTH

H CLOSE HESSELTINE, M.D., CHICAGO, CHAIRMAN
COMMITTEE

MAX BURNELL, M.D., FLINT, MICH., JENNINGS C. LITZEN-
BERG, M.D., MINNEAPOLIS, GOODRICH C. SCHAUFFLER, M.D.,
PORTLAND, ORE., ROBERT E. SEIBELS, M.D., COLUMBIA
S. C. LOUIS E. PHANEUF, M.D., BOSTON, CHAIRMAN OF
THE SECTION EX OFFICIO, PHILIP F. WILLIAMS, M.D.,
PHILADELPHIA, SECRETARY OF THE SECTION, EX OFFICIO

GENERAL STATEMENT

Shortage of man power and economic pressure necessitate the employment of millions of women in industry. Sufficient medical data are not available to draft final recommendations about the effect of various kinds of employment on the gynecologic or future obstetric health of unmarried or childless women, on the pregnant, puerperal or lactating women or on mothers with home and family responsibilities. However, it is common experience in industry that women absent themselves from work much more often than men and that the duration of individual absences tends regularly to be longer. The available data do not clearly assign the responsibility for this tendency directly to obstetric or gynecologic functions (although it has been taken for granted by some) as against ordinary causes of disability which are equally applicable to men. All of these relationships need careful study over an extended period of time.

Therefore, the present report is preliminary in character and contains recommendations on which there is already substantial agreement. The committee expects subsequently to submit additional statements from time to time as greater experience and more accurate observations become available.

ESSENTIALS OF MEDICAL SERVICE IN INDUSTRY

The increasing employment of women in industry will intensify demands for competent medical supervision, especially in those industries using women for the first time. The Council on Industrial Health of the American Medical Association lists the essentials for such service as follows:¹

A A physician who takes genuine interest in a properly conducted industrial medical department and who is willing to devote regular hours to services inside the plant

B Industrial nurses with proper preparation acting under the physician's immediate supervision or under standing orders, constitute the principal source of sustained industrial health activities for most small industrial concerns

C Industrial hygiene services, directed at improvement of working environment and control of unhealthful exposures provided by physicians and others under the guidance and assistance of the specialized personnel in the state and local bureaus of industrial hygiene

D A health program which will include

1 Good first aid, emergency, and subsequent medical and surgical care for all industrially induced disability

2 Good correlation with the family physician and other community health agencies for proper management of non-occupational sickness and injury

3 Health conservation of workers through physical examination and health education

4 Good records of all causes of absence from work as a guide to the establishment of preventive measures

Consulting services in industry commonly include dermatologists, ophthalmologists, surgeons, internists, neurologists, neurosurgeons, psychologists and psychiatrists and other recognized medical specialties. The committee recommends that competent gynecologists and obstetricians be included in the consulting services where substantial numbers of women are employed.

GENERAL HYGIENE FOR WOMEN IN INDUSTRY

Ordinary industrial hygiene activity, safety practice and medical or engineering control over conditions of work apply to men and women alike. However, additional safeguards have been set up in nearly every jurisdiction as supplementary protection for the health of women. Physicians called on to exercise supervision over employed groups should familiarize themselves with all applicable statutes or health codes. However, the committee does wish to emphasize the following special considerations:

A *Type of Work*—Generally women work at home in addition to a regular shift in the plant. A wife and more especially a mother may be engaged as many hours at housework as in industry. Such excessive burdens are undesirable, especially during pregnancy. Since rest is difficult in the home during the day, mothers should work either the day or afternoon shifts.

Women have been employed by almost every industry successfully. They are particularly suitable where manual dexterity is involved. This applies to work in the assembly lines, with small drills, with punch presses, at mailing and filing in the preparation of food in textile or weaving industries, in small arms plants and in many other war industries. Lifting, pulling, carrying or shifting weights should not be beyond a reasonable and comfortable capacity for the individual. The maximum units for weight lifting should not exceed 35 pounds probably. Weight factors should be

² Or obstetrician and gynecologist.

lower for the gravid individual and also for older women and those with vaginal wall relaxations or beginning prolapse.

B Working Garments and Equipment—The woman worker should have the same clothing protections as the man. Slacks will be preferable to skirts in certain types of work. Blouses with long dangling sleeves may be dangerous about machinery. It is equally important that appropriate garments and protection be afforded to those exposed to excessive heat or cold. The customary protection for the eyes, hands and the hair is self evident. In general, women should use low heeled comfortable shoes, and this is most important for those who are gravid.

C Optimum Hours of Work—The maximum number of hours for women employment has been established in many localities. The nature of the work as well as the urgency of the situation may influence somewhat the number of hours employed per day or per week. Ordinarily, women may be employed from thirty-six to forty-eight hours a week depending on the local statutes, the type of work and the individual's capacity.

D Industrial Sanitation—The standards for adequate lighting and ventilation are equally applicable here. An adequate number of toilets and lavatories properly maintained and reasonably accessible constitute part of the necessary rules of good hygiene. Rest-rooms where the pregnant, menstruating or ill women may rest or recline should be provided. Rest periods are desirable and may be conducive to more production.

E Supervision—Adequate supervision at the plant is necessary, particularly a foreman or forewoman trained or experienced in the supervision of women employees. The management of any plant not accustomed to the employment of women would do well indeed to consult plant physicians and others experienced in the problems of women employees before employing women. Even the placement of women in another division in the same plant may bring about new problems.

A matron or "councilor service" has been found unusually successful in several large plants where a large number of women are employed.

The evaluation of movement and monotonous work is one of the problems of the plant physician. Likewise, constant sitting or prolonged standing is more disturbing to the gravid patient. Adjustments should be made in such a fashion that the employee does not work in a strained position at benches, tables and machines.

TRANSPORTATION OF WOMEN TO AND FROM WORK

Transportation of women to and from work may be even more difficult than that of men. Adequate protections and shelters should be afforded women between the transportation system and the place of employment.

PHYSICAL EXAMINATION AND PLACEMENT

A General Recommendations—The general recommendations developed by the Council on Industrial Health apply. These are:³

Preplacement physical examinations should be complete. They should be used only for the purpose of assigning work adjusted to the physical and temperamental fitness of the applicant and to maintain safe and healthful employment for all employees.

Subsequent physical examinations should be complete enough to provide positive health protection for all workers and to safeguard public welfare. Repetition of such physical examinations must be determined by the physician in accordance with specific requirements.

In the interest of uniformity, physical examination forms are recommended. Personal records of this character are confidential and should be kept in the custody of the medical department. Access to these records should be granted only on request or consent of the examinee.

The examining physician should request the examinee with the results of all examinations or take steps to refer all conditions requiring correction to the physician of the worker's choice.

B Obstetric and Gynecologic Recommendations—At the time of the regular examination and history, special inquiry should be made about the breast and obstetric and pelvic conditions.

From the obstetric and gynecologic point of view, the opportunity is too good to be missed for as thorough an evaluation of the system as possible. For example, a thorough examination may elicit an early but serious lesion of the breast, cervix, uterus or adnexa. Other conditions may be revealed which are less serious but which should be reexamined at regular intervals as a health measure to the employee.

A thorough preemployment evaluation of the pelvic organs will permit better placement of the employee more appropriately, as well as to discover early significant and serious disease or altered physiologic states which are still subject to correction.

Women with relaxation of the pelvic structures or prolapse should be placed in work where the stress and strain of lifting or the prolonged effect of gravity can be entirely avoided.

The pregnant or lactating woman as well as women affected by sterility or habitual abortion, should be particularly protected against lead, mercury, arsenic, phosphorus, solvents benzene and homologues, volatile oils, nitrobenzene and explosives, x-rays and radium and other dangerous agents. Any substance or agent which might injure the liver or kidneys may precipitate extremely serious complications during pregnancy or in relation to pregnancy and lactation. Women who have had toxemia in previous pregnancies or difficulty with fertility or completing a pregnancy should avoid employment during pregnancy.

MFSTRUATION

Many women have little or no incapacitation during menstruation. Those with mild distress may be benefited by dietary improvement, by the avoidance of unnecessary physical and strenuous activities for a few days prior to the expected period or by the administration of mild sedatives and analgesics, under the direction of the plant physician or the employee's personal physician.

Severe cases of dysmenorrhea may require the attention of the specialist. Dysmenorrhea is a symptom and results from many conditions such as pelvic inflammatory states, endometriosis, pelvic neoplasms, cervical stenosis, maladjustment, hormonal imbalance, migraine and allergic states. Adequate rest facilities at the plant are desirable and a brief rest may cause only a slight interruption in the day's work rather than a loss of several hours. Hot applications to the lower abdomen or back may be helpful. Stimulants as coffee, tea or other hot drinks are sometimes beneficial.

For those who must lose one or two days regularly because of dysmenorrhea, a rearrangement of work schedules so that an extra day could be worked on

³ Outline of Procedure for Physicians in Industry J. A. M. A. 118:895 (March 14) 1942.

one or two weeks prior to the catamenia would be very helpful. In this way the woman would not be penalized because of her menstrual distress.

In a few instances efficiency may be so greatly lowered at the time of the menstrual period that the woman should not work. If flexibility in hours or days of work could be arranged there should be more efficient and better production.

A change in climate or altitude may be associated with an increase in menstrual distress, alteration or abnormalities, as dysmenorrhea, amenorrhea, menorrhagia or metrorrhagia. Likewise positions of responsibility, tension or worry may be associated with altered menstrual action.

On the other hand, menorrhagia or metrorrhagia may be the first symptom of cancer or neoplasm. Thus, careful consideration should be given to all complaints and appropriate investigation made by the employee's physician or obstetrician and gynecologist.

MENOPAUSE

Because of nervous and vasomotor instabilities, increased excitability and increased susceptibility to fatigue, women in the climacteric may need special consideration. Estrogenic therapy or sedatives may be extremely beneficial, particularly when there is disturbing noise, excitement or tension, as well as maladjustment to employment or to associated workers, to supervisors or to environment. The menopausal syndrome is certainly not caused by employment and the treatment is not primarily an industrial problem.

Not uncommonly prolapse or cystocele and rectocele become worse near or after the menopause. Consequently women in the postmenopausal period should be particularly evaluated for placement in industry and urged to profit by periodic examinations.

PREGNANCY

A Normal Pregnancy—Normal pregnant women need reasonable activity, but when employment is necessary stresses and strains should be eliminated. Continuance of employment is common practice in the first half of pregnancy or perhaps longer, depending on the woman's physical tolerance to the type of work. The pregnant employee must not be overburdened by home duties. Each pregnant employee should have individual consideration by her obstetrician and by the plant physician as to the hours and duration of the employment as well as to type of employment.

As the pregnancy advances beyond the twentieth to twenty-fourth week of gestation the woman becomes progressively more awkward and thus must avoid climbing and walking where delicate balance is involved.

Pregnant women should have a regular shift of employment in order that their lives may be regulated for the greatest amount of rest and regular sleep. If the employment is improper or cannot be physically tolerated the patient must stop work or be transferred to more suitable activity.

B Leave for Pregnancy and Puerperium—The pregnant employee should not be employed after the thirty-second week of pregnancy (that is, within six weeks of term). It is believed that the discontinuance of employment in the last trimester would benefit many prospective mothers, if economic circumstances permit.

This committee recommends that each employee inform the proper authority in the industry about her pregnant state within the first trimester (three months),

that she obtain a statement from her physician to the effect (1) that her work is not contraindicated and (2) that she may work not longer than a given period of pregnancy. If contraindications to work arise, the employee's physician should notify the employer.

The patient should not return to work until six weeks after delivery and then only when her physician notifies the employer that she may return. If her return to work at six weeks is inadvisable because of her own condition or because her baby actually needs her at home she should request further extension of time.

C Antepartum Care—Every gravid woman should seek the advice of her physician or obstetrician in the first trimester of pregnancy. For the best interest of the patient, her own physician or obstetrician and gynecologist should administer all antepartum, obstetric and puerperal care. In case of emergency, of course, additional medical care should be obtained from the nearest available source.

Antepartum care consists of a complete history, physical examination, pelvic examination, pelvic measurement, serologic test for syphilis, hemoglobin test, usual urinalysis and blood pressure recording. Ordinarily, return visits need not be oftener than once every three weeks until the thirty-second week of pregnancy and then every two weeks until the thirty-sixth week after which weekly visits may be required. A urine specimen must be left at each visit, blood pressure taken and the weight recorded. In the last month or so of pregnancy it is good practice to note the position and size of the fetus.

D Complications—Unintentional abortion is the most likely obstetric complication in the first trimester of pregnancy and it may have no relationship to the employment. These accidental abortions result perhaps more often from abnormal or diseased ova and not because of work or activity. Excessive vomiting is the second most likely problem in the first trimester.

The last trimester is complicated most often by toxemia of pregnancy, placenta previa or abruptio placentae. All of these obstetric emergencies are incompatible with employment of any kind and need immediate treatment.

The midtrimester is a comparatively safe period but any complication may arise at this time, as well as any other, such as anemia, hyperthyroidism, diabetes, tuberculosis, syphilis, gonorrhea, heart disease, hypertension and nephritis, pyelitis, neoplasms (both benign and malignant) and many other conditions.

Other complications will also alter the program. Genital tract infections may require treatment from every two to seven days. Antisyphilitic treatment should be weekly. The management of medical complications will necessitate a specially devised program. In the event of excessive weight gain or evidence of toxemia, special instructions must be given. These are only some of the conditions that the obstetrician may encounter in the care of his patients.

LACTATION

Unless special facilities are available, it is unsatisfactory or impossible for lactating mothers to work and continue to nurse a baby. If sufficient facilities are arranged ample time must be allowed for nursing and for the patient to obtain food and fluid. The employer should have a statement from the employee's physician prior to employment of a nursing mother that there is no medical reason contraindicating employment.

CARE OF CHILDREN OF MOTHERS IN INDUSTRY

If mothers are employed, arrangements must be made to provide suitable facilities and properly trained personnel to care for dependent children safely. Such care will depend on the size and age of children and the hours of the mother's employment. Infants will require a different type of attention than older children well along in school. Children attending school will need adequate supervision before and after school hours for the assurance of adequate diet, proper clothing and other protections until the mother can take over the responsibility. Special study of this problem must be undertaken wherever these social problems arise.

CONTROL OF COMMON RESPIRATORY INFECTIONS

CHRISTLER S. KIEFER, M.D.

BOSTON

To say that respiratory infections are responsible for more loss of time from industry than any other single group of disorders is only to repeat a well known statement. This subject has been discussed on many occasions, and at the Third Annual Congress on Industrial Health which was held by this group in 1941 it was the topic of a most enlightened symposium.¹ Such topics as the incidence and economics of acute respiratory infections, the role of the physician in the control of respiratory infections and air conditioning were discussed.

Today I propose to discuss some of the methods which are available for the prevention and control of these infections. While it will be admitted at once that there is no completely effective method for their prevention and control at least more is known today about certain aspects of the problem than was the case some years ago. In regard to treatment we are on much safer ground, great strides have been made within recent years. I shall confine my remarks to the common cold, epidemic influenza and pneumonia.

THE COMMON COLD

It is now agreed that the common cold is caused by a filtrable virus and that it is the most frequent of all respiratory infections. It is a widespread infection and occurs throughout the world. Epidemiologic studies disclose that the frequency of colds is between two and three per person each year. It has been demonstrated by Dochez and his associates² as well as others³ that the virus of this disease promotes and furthers infection of the respiratory organs by pathogenic organisms such as the pneumococcus, hemolytic streptococcus, staphylococcus and influenza bacillus. It also facilitates the distribution of these bacteria in

the community and establishes a background for the occurrence of severe outbreaks of respiratory diseases.

Before saying anything about the prevention of colds, I will cite a few pertinent facts concerning their pathogenesis. The incidence of colds in the United States varies throughout the year and the morbidity rate is cyclic. There are three main peaks of incidence each year: the first in January and February, the second in April and May and the third in September and October. The epidemic occurring in the spring tends to be the mildest while that occurring in January and February is the most serious as measured by absence from work and severe complications. Infection is frequent in families, in schools, in industries and where overcrowding is common.

The common cold is highly contagious and the incubation period is short, varying between twenty-four and thirty-six hours. The infected individual can transmit the infection to others only during the early stages of the disease, that is, during the first day or two after the onset of infection. The most infectious period is the first day and it is known that a patient may actually infect others from four to six hours prior to the development of symptoms.

Carriers of the virus of the common cold are thought to be infrequent but on this point there is very little precise information. The opinion prevails that carriers are encountered only rarely. This is a matter which needs more investigation.

Once colds become prevalent in any community many susceptible people who are exposed to an infected person come down with the disease. The degree of susceptibility and resistance varies from one individual to another and from year to year. This is brought out in epidemiologic studies in families and in schools. Resistance seems to increase with age since there are fewer colds in the elderly than in the young.

A certain degree of immunity, as judged by resistance to reinfection, develops as a result of a cold but it is of short duration. In the experimental studies of Dochez and his associates⁴ it was found that resistance lasted about a month in the chimpanzee. In man, it was estimated by Paul and Freese⁵ to be not less than twenty-three days with an average of about seven weeks.

It seems clear then that the common cold is due to a filtrable virus and that a part of its action is to promote secondary bacterial infection of the respiratory organs. It is cyclic in its morbidity and varies in its seriousness, depending on seasonal factors and the frequency and incidence of secondary invaders. It is highly contagious and while one attack confers increased resistance to reinfection this period is of short duration.

One of the puzzling features about the common cold in temperate and tropical zones is its cyclic morbidity. We are almost wholly ignorant of the factors that promote the dissemination of a virus in any community and cause outbreaks of the disease. It is well established that colds are contagious and are spread by contact infection and probably by the air, but it is completely mysterious why there should be sudden outbreaks of the disease. It has been postulated that

sudden changes in temperature and excessive chilling or wetting of the skin promote conditions in the respiratory passages that permit the virus to invade and then spread through the community. There seems to be little doubt that these environmental factors are of importance but their precise role remains unclear. The studies of Paul and Freese,⁵ carried out in Spitsbergen, and those of Paul⁶ on the nonmagnetic ship *Carnegie* shed some light on this problem. In Spitsbergen, which is an extremely isolated community in winter, it was found that an unfavorable environmental factor such as a sudden drop in atmospheric temperature, was not necessary for the development of an epidemic of colds. It was noted, however, that the arrival of the first boat of the shipping season was usually followed by an epidemic involving the whole community in a short time. This suggests that the introduction of the virus from outside is more important than the climate. Also it was noted by Paul and Freese that trappers who fell through the ice did not develop colds during the winter and spring but did so only if such an accident occurred after the men had been to town in the summer and fall. Such observations suggested that sudden chilling of the body may bring on an attack in a person who has had a recent infection or a recent contact, but only if such a condition accompanied the chilling. That chilling may predispose to colds in isolated groups, however, would seem to receive some support from the following observations of Paul. Outbreaks of colds were noted on the *Carnegie* when the ship entered a cold current from warmer waters even though it had been out of port for days or weeks. This suggests that exposure to cold may in some way activate the virus in a group after it has failed to produce infection for many days or weeks preceding the outbreak.

It seems plain that a more careful definition of the host and environmental factors which favor the spread and invasion of the virus of the common cold is necessary before the spread of this infection can be effectively controlled.

Prevention—Methods of preventing colds have been directed along several lines. It can be said at once that none of them are effective. Since it is as yet impossible to prevent the spread of the virus in the community, attempts have been made to increase the resistance of the host. Within recent years vaccines, vitamins and "hardening processes" have been investigated. These deserve individual comment.

Cold Vaccines—In attempting to reduce the number of colds in susceptible persons, vaccines containing a wide variety of micro-organisms commonly found in the respiratory tract have been used. Since the common cold is due to a filtrable virus and the organisms included in the vaccines are now believed to be of secondary importance, it is not surprising that these vaccines, whether given by mouth or by injection, have been a great disappointment. In spite of the many supporters of this method of prophylaxis, it is generally agreed that the incidence of colds is no less following their use than in groups of nonvaccinated controls, and there is good evidence that these vaccines may produce little or no protection against diseases of the upper respiratory passages.⁶

Since so-called cold vaccines are still widely used, it is well to review the evidence on which the foregoing

statements are based. To Diehl, Baker and Cowan⁷ belongs the credit for clarifying the position of cold vaccines. In two reports, one appearing in 1938⁷ and the other in 1940,⁸ the following results were recorded. In 1938 it was found that in a group receiving a polyvalent vaccine by mouth the incidence of colds was the same in the vaccinated as in the control group, and the same was true when Rosenow's streptococcus vaccine was used. In a third group receiving vaccine subcutaneously there were 25 per cent fewer colds per person than in the control group. This difference was noted during both years of the study and was considered statistically significant. Practically, however these authors expressed the opinion that this reduction of 25 per cent in the average number of colds in the group was not sufficiently great to justify the time and expense involved in carrying out the program. In the second report, appearing in 1940 it was concluded that in a group of cold susceptible students at the University of Minnesota there was no evidence that heat killed vaccine was of any value in preventing the common cold.

As the virus of the common cold promotes the growth of micro-organisms in the respiratory passages, it might be hoped that vaccines made from these organisms would reduce the number of complications. Experiments designed to shed light on this question have been carried out by Dochez and his associates⁶ and by Diehl, Baker and Cowan.⁷ The results have not been very encouraging. The former investigators studied a group of 20 infants in an institution and gave vaccine at weekly intervals over a period of months. Nine injections were given in the autumn and a similar number in February and March. Another group of infants of the same age and living under the same conditions were observed as controls. The results of this carefully controlled study were of great interest. There was no reduction in the number of simple colds or of respiratory infections associated with fever in the vaccinated when compared with the nonvaccinated. There was, however, an apparent reduction in the severity of the infections as judged by the duration of the fever, which was shorter by 40 per cent in the vaccinated than in the nonvaccinated. There were 5 cases of pneumonia among the nonvaccinated group and 1 case in the vaccinated group. Dochez and his co-workers concluded that the protection against febrile respiratory complications of a cold was incomplete and that the technic of carrying out such immunization so time consuming and burdensome that this method did not seem promising for general use.

Diehl, Baker and Cowan⁷ were unable to find any difference in the incidence of complications in the vaccinated and the nonvaccinated. The slight difference in the two groups may have been due to the difference in ages and in environment. One group lived in an institution, the other was composed of students in a university.

On the whole, then, one can say without fear of contradiction that the results obtained from cold vaccines have been disappointing. The vaccines have failed to prevent colds, and they have failed to lessen the number of complications except when given repeatedly over a long period of time.

Vitamins—Deficiency states often predispose to infections, but the supplying of extra vitamins and other food elements to the person who shows no signs of deficiency disease does not protect him against respiratory infections, including colds. Carefully controlled studies have been made recently by Cowan, Diehl and Baker⁹ and by Kuttner¹⁰. The evidence is good that large doses of vitamins A, B₁, B₂, C and D and nicotinic acid, or vitamin C alone, have no significant effect on either the number or severity of upper respiratory infections when exhibited to young adults who are on a reasonably adequate diet. Besides these observations, Sutliff, Place and Segool¹¹ were able to show that large doses of vitamins A and D failed to prevent complications in established hemolytic streptococcus infections of the throat. Experiments such as those carried out by the Minnesota group⁹ are of the highest importance, since here was a group of investigators sincerely interested in methods of preventing and treating colds, who have devoted a number of years of study to this most important problem. They understand the significance of a controlled experiment. A careful study of their data leaves no doubt in the minds of the most critical observer that vitamin therapy in the group studied by them was of no value as far as either the number or the severity of colds was concerned. There is no reason to believe that their experience is unique.

Hardening Processes—A number of procedures have been recommended from time to time which have as their objective the conditioning of the body to sudden changes in external temperatures of the skin, such as cold shower baths every morning and exercise outdoors followed by hot and cold shower baths. Controlled experiments on this subject have been carried out by Gafafer,¹² who was unable to show any lower incidence of colds in people who followed these practices when compared with a group who did not.

To sum up, it can be stated that vaccines containing the ordinary organisms found in the nose and throat are of no practical value in the prevention of colds. There is no conclusive evidence that they even shorten the course of a cold or prevent the development of secondary infections. It is also true that vitamins fail to prevent colds, at least in a group of cold susceptible people. To date, all other measures have failed to influence the frequency of colds, and we are forced to the unhappy conclusion that at present there are no effective methods available for the prevention of the common cold. Personal hygienic measures and the avoidance of excessive chilling and sudden changes in temperature, especially at a time of year when colds are prevalent, may aid in reducing the total number of colds in some individuals. Avoidance of exposure to colds is important but not always practicable. Every effort should be made to practice hygienic measures, such as washing the hands before meals and avoidance of direct contact with persons with colds. Once colds have developed, relief can be obtained by rest, from codeine and papaverine, and through symptomatic

treatment. Undue risks should not be taken, since colds are often followed by pneumonia and other serious respiratory illness.

Continued study of the factors influencing the development and spread of colds is needed, such as a search for adequate and effective chemotherapeutic agents.

INFLUENZA

Terminology—Since it has been demonstrated repeatedly that the clinical picture recognized as influenza is not a single etiologic entity, it has been suggested by a group of prominent students of the problem¹³ that a more precise nomenclature be used. They suggest that influenza be identified according to the virus which is isolated from the patient by such terms as "influenza A" and "influenza B." When a disease occurs in which the clinical features are like those of influenza but it is impossible to isolate a specific virus, it is suggested that the name "clinical influenza" be used.

Clinical influenza occurs as a sporadic, epidemic or pandemic infection. The sporadic and epidemic forms which have occurred in this country and elsewhere within the last few years are due in many instances to a filtrable virus designated as influenza type A and type B respectively. Whether the pandemic disease which occurred in 1918 was due to the same virus is not known. There seems little reason to doubt, however, that it was due to a virus infection. Of all the epidemic respiratory infections, influenza is perhaps the most important, since it can virtually paralyze the activity of civilian and military units. It not only causes great loss of time from work but, since it predisposes its victims to pneumonia, it is responsible for many deaths. In the United States alone in 1918 the attack rate varied from 150 to 280 per thousand, and the total number of deaths reached 500,000. It is no wonder, then, that this pandemic is remembered as one of the worst calamities affecting any nation.

Stimulated by this experience, a number of agencies, among them the Influenza-Pneumonia Commission of the Metropolitan Life Insurance Company, the International Health Board of the Rockefeller Foundation, the Chemical Foundation, the Commonwealth Fund and the National Institute of Health, and a number of scientists working in our leading universities and research institutes began an intensive study of the cause of influenza together with an investigation of methods of prevention and control. Within recent years, great advances have been made. We now know that some forms of influenza are caused by a filtrable virus which can be isolated and used as a vaccine. We also know that there are available both antipneumococcus antiserum and sulfonamide drugs for the treatment of pneumonia, which is so often a complication of influenza. While the sulfonamides have no demonstrable effect on the influenzal infection, they are powerful agents in the treatment of pneumonia and there is some evidence that they may aid in its prevention.

In an attempt to prevent influenza, three lines of investigation have been prosecuted: the use of vaccines, the control of air borne infection by means of ultraviolet irradiation of air and the use of propylene glycol vapor, and the use of immune serum.

Vaccines—As soon as a virus was isolated from cases of influenza, attempts were made to develop a vaccine which would produce protection against infection. It was soon found that neutralizing and protective

antibodies could be produced in animals vaccinated with the virus. A wide variety of vaccines have been used in man to stimulate antibodies and protect patients against attacks of influenza.¹⁴ Without attempting to review in detail the literature on this subject, I can make the following statements. Vaccines made of influenza virus call forth an antibody response in the recipients but they do not completely protect against attacks of influenza. The evidence is good that the incidence of the disease is reduced in some groups and the duration of the disease is shortened. Stokes and Henle¹⁵ have pointed out that the higher the titer of antibodies in the blood, the lower the incidence of influenza. It would appear that the presence of antibodies in the circulating blood aids greatly in the protection against attacks of influenza but from many studies it seems evident that there are often other factors aside from the antibody titer in the circulating blood which are important in preventing infections. For example Francis¹⁶ has found that nasal secretions from some human subjects contain material which neutralizes the influenza virus. Such an observation suggests that local as well as general factors are important in the resistance of individuals to the invasion of the influenza virus. The studies which have been carried out so far with vaccines give considerable promise and are a real step in advance.

Control of Air Borne Infection—Aside from increasing individual resistance to infection, attempts have been made to prevent the spread of the influenza virus and other infective agents by means of ultraviolet irradiation of air and propylene glycol vapor. It was first demonstrated by Robertson and his associates¹⁷ that the vapor of propylene glycol, even in a dilution of 1:50,000,000, was effective in destroying air borne bacteria and the human influenza virus A, as demonstrated by plating and animal tests. Harris and Stokes¹⁸ and Stokes and Henle¹⁹ have recently reported their results with the effect of this vapor on the incidence of respiratory infections in a convalescent home for children and in the prevention of air borne infection of mice by influenza A virus. These preliminary observations leave no doubt in any one's mind that this vapor is an effective means of sterilizing or reducing the bacterial counts in the air of hospital wards. They are also indicative of the great potential value of this method in the prevention of cross infection,

especially when persons live in close contact with others indoors. When the effect of ultraviolet irradiation was compared with that of propylene glycol vapor it was demonstrated that they were almost equally effective in the prevention of air borne infection of mice by influenza A virus. These experiments suggest that both ultraviolet radiation and propylene glycol vapor spray are agents which deserve extended trial in the prevention of the spread of respiratory infections.

Immune Serum—The use of immune serum locally in the nasal passages has also been explored. Stokes and Henle¹⁵ have reported encouraging preliminary results with this method in experimental animals which indicate that it deserves a trial in man.

It can be seen, then, that intensive investigations are being carried forward at the present time which have as their objective the prevention of influenza. The results which have been obtained so far are extremely encouraging, and there are good reasons for believing that further advances will be forthcoming in the near future.

PNEUMOCOCCIC PNEUMONIA

Great strides have been made in the treatment of pneumococcic pneumonia but very little has been accomplished in its prevention. It is now acknowledged that the death rate from pneumonia has decreased considerably since the introduction of sulfapyridine in 1937. This decline has occurred in spite of the fact that there has been no decrease in the incidence of the disease. Concurrent with a reduction in the death rate there has occurred as a result of modern treatment a decrease in the total number of days of illness. For example, Ungerleider and Gubner¹⁹ of the Equitable Life Assurance Society of the United States, in commenting on the economic aspects of pneumonia with reference to the prevalence and duration of illness in the years before and since the development of the sulfonamides have pointed out the following facts. When the incidence of pneumonia in the three years preceding the use of the sulfonamides was compared with its incidence in 1939, 1940 and 1941, it was clear that there was no decrease, indeed there appeared to have been an increase. Secondly, the duration of illness has been greatly reduced, that is to say, the average period away from work in 1941 was 35 days, compared with 45 days in 1935. The modal or most frequent duration of illness in 1941 was 27 days, compared with 38 days in 1935. The experience of others is in agreement with these findings.

There seems to be no doubt, then, that with modern methods of treatment the total number of days lost from work by persons who develop pneumonia can be greatly reduced. In the aggregate this results in great economic savings to industries, employees and insurance companies.

Cause of Death—We may now turn our attention to the question of the cause of death in patients with pneumonia, since it is only by a knowledge of these factors that improvement can be made possible. It is well known and widely recognized that the prognosis in pneumonia depends on the summation of many factors, including age, sex, season of year, occupation, bacteremia, number of lobes involved, type of pneumococcus, complications, pregnancy, debilitating diseases and the time and type of treatment. In order

to gather more information concerning the factors responsible for death among a group of industrial policyholders, a study along these lines was made by the Metropolitan Life Insurance Company and published in 1941.²⁰ It was found that the age of the patient, delay in calling a doctor, premature discontinuance of chemotherapy and complicating diseases were vital factors in influencing the death rate. Thus being the case it would seem necessary to stress to the patient as well as to the physician the importance of early and thorough treatment. In this way the death rate may be reduced still further.

Prevention—What can be done about the prevention of pneumonia? It has already been stated that very little has been accomplished in this direction and the disease continues to remain a major factor in loss to industry through illness. In any discussion of the prevention of a disease, it is well to ask how it is acquired and what factors predispose to its development. While the factors of susceptibility to pneumonia are not all clearly understood a number of advances have been made recently in the epidemiology of pneumococcal infections. The reviews of Finland²¹ are recommended for reading and study. In these reviews it is stated that both carriers and cases of pneumonia serve as foci for the spread of the disease, carriers being more important than cases. Finland also asserts that the occurrence of pneumococcal infection is dependent on the individual's susceptibility to the particular strain of pneumococcus with which he comes in contact. While the aspects of this underlying susceptibility are not all understood, it is recognized that the following features are important: excessive fatigue from overwork and inadequate rest, excessive chilling following exposure to cold or wet, sudden chilling when overheated, the presence of other infections such as colds, influenza, bronchitis and acute or chronic alcoholism. To these of course, should be added the extent and intimacy of contacts with cases or carriers. The spread of pneumococci is greatest within families, in barracks or in open dormitories where the chance for intimate and repeated contacts is possible.

Recommendations for Control—What specific recommendations can be made for the control of the spread of pneumonia and pneumococcal infections in general? A few of the chief points may be enumerated:

- 1 Education of the medical profession and public concerning the dangers of the spread of pneumonia by contact with cases of pneumococcal infection in the home or elsewhere.
- 2 The isolation of all active cases.
- 3 The adequate medical care of colds and bronchitis.
- 4 The destruction of ill discharges from the nose and throat.
- 5 The early recognition, reporting and isolation of the infective agent.
- 6 The prompt and effective use of chemotherapeutic agents.
- 7 The avoidance of overcrowding.

Predisposing factors leading to the spread of pneumonia in industries must be studied carefully with an attempt to eliminate each one as far as possible.

ATYPICAL BRONCHOPNEUMONIA OF UNKNOWN ETIOLOGY

In conclusion something should be said about a group of respiratory infections which has attracted considerable attention within the past few years. These conditions have been described under a variety of names such as virus pneumonia, atypical bronchopneumonia of unknown etiology and acute pneumonitis. It is plain that they do not represent a single etiologic group since several different viruses have been isolated from clinically identical cases. In the vast majority of instances, however, no specific agent has been isolated.

The prevailing type is acute in onset, with fever, prostration and cough. It is highly contagious and the incubation period lasts from ten to fourteen days or longer. The course is extremely variable, but it tends to be self limited, lasting from ten days to two weeks. Complications are few and the outcome is usually favorable. The course of the disease is not altered by chemotherapy.

Since the cause of this disease is unknown, its prevention is difficult. However, the same general measures should be taken in an attempt to control it as are recommended for the control of other types of pneumonia.

THE OLDER WORKER

A. J. CARLSON, M.D.
CHICAGO

While it is true that modern war, the organized killing of our fellow men and wholesale destruction of the products of human toil, can be waged most efficiently by men between the ages of 18 and 35, the industrial needs of this war have already demonstrated anew several important facts about the older industrial worker, facts well known but forgotten or ignored in the plethora of peacetime impotence and in the fog of a social philosophy according to which a life of leisure is better and society must feed, clothe and house all idle chicks whether or not these chicks can scratch. These facts are:

1 The physiologic age of the worker is not synonymous with his chronologic age, owing to the individual variables in heredity, mode of living, accidents and sequence of disease.

2 While most workers past 50 or 60 years of age have somewhat less physical strength and physical endurance as well as some impairment of hearing and vision, this may be compensated for in many forms of labor by the greater skill and experience and the decrease in youthful dissipation.

3 By keeping in idleness older workers who can still perform useful labor, we are not only wasting valuable human resources but we are contributing to biologic parasitism and degeneration of human society. For man is no exception to the biologic law that existence without effort, without struggle, impairs the species.

4 By forced idleness of the increasing army of older workers in our midst we are forging a dangerously weak link in that large fraction of society whose experience, wisdom and relative unselfishness could guide those with less experience and wisdom. For when a person is shunted out of the dynamic current of life, courage and incentive are at low tide.

5 One element in the philosophy of organized or union labor, namely equal hourly wage for all workers in each special trade, must share part of the blame for the past practice of discarding the older worker by the management of industry. Even though all workers are not equal in skill and efficiency, and in spite of the fact that the practice of organized labor tends to gear the rate of all workers to the slowest in the group, there comes a day when the older worker in many given tasks cannot keep pace even with the slowest and least efficient younger comrades. Economic management calls for dismissal of the older worker at that point. If wage in proportion to performance was recognized as a fundamental principle, the older worker could taper off in industry, just as the young apprentice works himself gradually up in skill, performance and remuneration. From my knowledge of human nature another destructive effect on morale, efficiency and joy of living results from the practice of gearing the most efficient to the rate of performance of the least efficient. On that plan the ablest worker will seldom, if ever, experience the joy of performance according to his superior ability or the growth in skill commensurate with his ability. This not only is a waste of precious human resources but tends to make lives humdrum that could be enriched by the daily challenge and joy of more and better performance. For the ablest worker to be geared to mediocrity, to do less than his best, is bad psychology for our ablest people and is, so far as I can see, of little or no aid to the less able fellow citizen or to society. I speak not without experience. I was a firm hand and a labor union carpenter before I became a college student, an investigator and a teacher in the medical sciences.

Under more primitive and biologic conditions of human life, as in life on the farm and in agriculture in general, work and responsibility of children and youth have their normal biologic upward curve, as is the case among all wild animals who have to scratch for their living. Under similar conditions of life, as on the farm, men and women past 50, 60 or 70 years also find their niche of productive work, happy in the knowledge that they still have a part in the stream of life. Biologically, man grows in understanding and physical and mental efficiency from birth up to 25 or 30. Then there is a plateau of efficiency for some twenty years, health being present. Then the reversal of the youth curve sets in, the gradual impairment of the physical and considerably later even of memory and of mental efficiency. A civilization, a social or an economic system that discards men and women of 50 or 60 as no longer a link in the chain of human labor, as no longer productive physically and mentally, I say such a civilization, such social and economic systems, are thoroughly unbiologic, thoroughly wasteful and thoroughly cruel and inhuman to our fellow men at the later decades of life. A man or a woman in modern industry, trained to do, and for twenty or thirty years having done only one such small thing as fitting a screw on a certain size nut for eight hours a day, may not be able to perform that mechanical feat at the standard rate when past 50 or 60. But it is a terrible reflection on our education if that man and woman past 50 or 60 cannot do something else of value to society and to themselves. And it is certainly no indication of intelligent planning on the part of such society if opportunities for such work are not afforded. In fact tasks for which men and women past 50, 60 and 70 are thoroughly capable lie all around us like mountains

but we do not see them. Social security for our aging population is all right in principle, but it should take the form of labor for which these people are capable and not the form of pay for doing nothing.

In industrial tasks calling for maximum performance of the entire machinery of the human body, the older worker by and large will be increasingly handicapped by the sequelae of accidents and disease, despite all efforts of accident prevention and our growing knowledge and skill in medicine. Apart from and in addition to these factors, what are the inevitable and unavoidable aging changes of man rendering him less fit, if not unfit to labor? When and how speedily do these aging changes come on in the individual? Do these aging changes or impairments constitute a bar to all useful labor? Can industry be organized so as to make fair and adequate use of men and women handicapped by age alone? Is there no alternative to the relegation of men and women past 50, 60 or 70 years of age to the scrap heap of idleness and the dole, to parasitism and charity? All age changes come on gradually. Those body changes with age involving the strength and endurance of the skeletal neuromuscular mechanism and the senses of hearing and vision are probably the most significant for the industrial worker, but it must also be kept in mind that these systems are all dependent on a good diet, a good intestine, good blood, good kidneys and good lungs. The human body is a machine. Any weak link tends to impair all the other links. Some age impairments appear as early as the third decade. If all industrial labor was physically as exacting as prize fighting, marathon running or professional football, nearly all workers would be retired at 35 years of age.

Progressive age changes, not as yet shown to be due to specific diseases are

- (a) Gradual tissue desiccation
- (b) Gradual retardation of cell division, capacity or cell growth and tissue repair
- (c) Gradual retardation in the rate of tissue oxidation (lowering of the basal metabolic rate)
- (d) Cellular atrophy, degeneration, increased cell pigmentation and fatty infiltration
- (e) Gradual decrease in tissue elasticity and degenerative changes in the elastic connective tissue
- (f) Decreased speed, strength and endurance of skeletal neuromuscular reactions
- (g) Decreased strength of skeletal muscle
- (h) Progressive degeneration and atrophy of the nervous system, impaired vision, hearing, attention memory and mental endurance

THE NEUROSKELETAL SYSTEM

The gradual slowing and weakening of reflexes and general body activity in the aging mammal is so obvious as to be well known both to physicians and to laymen. Decreased functional capacity both in the nervous tissues and in the skeletal muscular tissue seems to be at the base of this gradual decline. Actual atrophy of the Purkinje cells of the cerebellum has been described in the aged and, since this part of the nervous system is seriously concerned with skeletal muscle tone and coordination of skeletal muscle contractions, it may be a factor in the growing muscular weakness of old people irrespective of the cause or causes of this atrophy in the cerebellum.

As regards the cerebrum of aged people, general atrophy has been described especially in the frontal and occipital lobes and actual disappearance of cells in some of the layers of the cerebral cortex, as well as pigmentation and fatty infiltration of the nerve cells and actual

hyperplasia of the neuroglia cells. Similar degenerative changes with age occur in the spinal cord, that is, atrophic pigmentation, actual loss of cells and degeneration of the axons of many ventral horn cells. In the case of the brain, thickening of the meninges occurs with advancing age, but it is difficult to see how this in any way should interfere with nervous action or nervous function.

Recent investigations appear to demonstrate a very gradual but significant decrease in the myelinated fibers of the dorsal nerve roots with advancing age. This must be secondary to an atrophy and death of spinal ganglion cells and is probably the basis of the reduction in cutaneous and protopathic sensibility of aged people. The sense of pain seems to be the least affected by aging. In view of such evidence of atrophic and degenerative changes in the central and peripheral nervous system irrespective of the primary cause or causes of these changes, it is not surprising that neuromuscular weakness, slowing of the reaction time and decreased capacity to learn are part and parcel of the physiology of aging. The speed of learning seems indeed to decrease gradually in man from the fourth decade on. But this handicap of the aged is on the whole more than made up for in some individuals by their greater speed of conclusion and evaluation of a new experience.

There is very little evidence of aging changes in smooth muscle, which seems on the whole to retain its normal histologic character into advanced old age. The diminished tone in smooth muscle, as may be seen in the blood vessels in the intestine and the smooth muscles of the skin and other structures in old people, may be secondary to the impairment in the nervous system that has been indicated. But not all the impairment of body motility with age can be ascribed to degenerative changes in the nervous system itself because the striated skeletal muscle system shows fatty infiltration and brown atrophy with advancing age. The strength of the biceps at the sixth decade of life is only about 50 per cent of that at the age of 25 to 30. The trunk muscles decline in power somewhat slower. However, the recent investigation by Kuho (1938) reports little evidence of decrease in muscle strength and endurance in people that would ordinarily be called old, that is, people 70 to 90 years of age. This is just another illustration of the individual variations in the chronologic age appearance of the aging processes. There is some increase in connective tissue and elastic fibers in the skeletal muscle of old people and there is clear evidence of desiccation, that is, decrease in intracellular fluid. But in this respect the skeletal muscle of the aged falls in line with all the other tissues of the body.

VISION AND HEARING

Because of the accessibility of the organs themselves and the availability of quantitative tests of function, we have more accurate information regarding the aging changes in the physiology of the eye and the physiology of the ear than in the case with most of the other systems in the human body. In the case of vision there is a gradual decrease in visual acuity (central vision), a gradual narrowing of the visual field, as well as a slowing of the dark adaptation (peripheral vision) and a gradually higher threshold for light stimulation for man past the fourth decade. The narrowing of the visual field is probably due to the actual degeneration of the nerve cells (cones), starting in the periphery of the retina. We are not yet in a position to say whether

these visual impairments occur independent of, or are secondary to, impaired retinal circulation. It is equally well known that the incidence of cataract increases with aging irrespective of whether or not the tendency to cataract formation is hereditary. Arterial sclerosis would undoubtedly accelerate any such hereditary weakness, and so would certain faulty diets and certain endocrine and other metabolic disorders. The gradual decrease of the elasticity of the lens is another well known and accurately measured phenomenon of aging man, with the exception that diminution in lens elasticity actually starts in childhood and practically all lens elasticity is lost before 60 years of age. The lens continues to grow at the periphery (vertex) and thus approaches closer and closer to the cornea with advancing years. At the same time the material at the center of the lens becomes more dense. Both of these factors and the lens swelling from increased water content, are responsible for the well known phenomenon of so called second sight of people 60 years of age and beyond. This lens change tends to counteract the presbyopia, or impairment of accommodation in hyperopes due to the loss of lens elasticity. Other age changes that may contribute to the gradual impairment of vision with age are diminished translucency of the cornea, the arcus senilis and the vitreous humor. It need not be pointed out that the retina being actually a lobe of the brain, is necessarily seriously impaired by local vascular pathologic change as is any other part of the brain. However, because of the accessibility of the retinal vessels to direct inspection we have probably earlier factual information regarding such pathologic change in the retina than we have in most of the other deep organs of the body.

HEARING

From the age of about 20 on there is a gradual loss of acuity to all tones but the loss of sensitivity is greater to the high tones. This deterioration of hearing is somewhat greater in the male, but the degree of retrogression is not predictable on chronologic age, as some people at 80 have no greater auditory impairment than other normal people at 50. This impairment of auditory acuity is present even when tested by bone conduction. The cause for this decline in auditory acuity appears to be a gradual but distinct atrophy of the nerve cells in the basal coil of the cochlea. But anemia, due to incipient arterial sclerosis, may also be a factor, since in experimental anoxia the perception of the high tones goes out first.

In the light of all these facts, one would expect that intellectual capacity should decline parallel with neuromuscular strength and endurance. According to all existing evidence, this is not the case. This exception is probably due to the significant role of experience especially in the case of complex intellectual problems.

THE DIET OF THE OLDER WORKER

While we do not know what may be the optimum diet for optimum efficiency for any age, we do know enough to say with certainty that the older worker will keep most fit by eating enough good food to avoid underweight and avoid eating so much food as to become obese. Life insurance statistics show clearly that definite underweight as well as definite obesity shortens the life span. Common experience demonstrates that both impair physical endurance and performance. It is not difficult to understand why ingestion of food to the point of obesity is injurious to people with reduced factors of safety in the matter of insulin pancreas, sugar and fat metabolism. Such dietary excesses

damage by overwork already impaired mechanisms. But in the absence of diabetes, actual or incipient, why does obesity, maintained for years, initiate or aggravate cardiovascular, renal and other disorders that shorten the life span? While the answer to these questions is being sought by experiments and accurate observation on mice and men, prevention of obesity in all workers past 30 appears to be a prophylactic imperative, a must.

From time to time financially fortunate and humane fellow citizens provide funds for "old peoples' homes." I hope that some financially fortunate, humane and farsighted fellow citizen will soon provide the National Research Council with a fund of \$1 000,000 to be used toward learning what is the optimum diet for old people—old workers on the farm, in industry in business and professions as well as those in old peoples' homes.

We know that the digestive secretions decline with age. The frequency of achlorhydria rises gradually in the population even past 30. What this means in the way of diet and nutrition of the older worker is not yet known. Dr. Edward L. Tuohy¹ recently published an excellent review of the known and the unknowns in "Feeding the Aged." There can be little doubt that persistent bad food habits will induce increasing impairments with the added years. The lower basal metabolic rate may call for fewer calories (less fats and starches) for men and women past 60 or 70, but the need for proteins, minerals and vitamins does not seem to be correspondingly reduced. Cash in the paltry sum of the price of a single super bomber would go far toward replacing with knowledge our present gaps and guesses as to the optimum diet for the older worker.

It should be quite clear to all informed people that normal aging strikes no man with the suddenness of an acute disease. We are not worth 100 per cent industrially today and worth zero tomorrow on our sixty-fifth or seventieth birthday. We grow old and inefficient just as we grow up and efficient over the years. We have discovered that useful work can be performed by people with disabilities more serious than those of normal aging, such as the blind, the deaf, the mute, people minus a hand, an arm, a leg or both legs. We readily admit that useful work suitable to the gradually aging worker is less readily provided in industry than on the farm. But it can be done, it has been done, it is being done even in industry. Such an experiment by the Dodge Division of the Chrysler Corporation in Detroit is described in some detail in *Forbes' Magazine* for November 1942 by Don Wharton. This experiment seems more significant as it was well under way (1934) before the present war and hence not carried financially by the present billions of federal war appropriations. The ninety-nine workers in the "Old Man's Division" of the Dodge plant average 66 years in age and some of them are past 80. But the fact that all these workers receive the same pay (93 cents an hour) makes me think that the department is not run on a strict economic basis, that the excess costs, if any, are charged against all the workers in that industry or added in the price of the product, a practice not uncommon and possibly justified in the better morale of the older worker. The general formula relating work to remuneration seems simple.

A The younger worker. Physical strength and endurance growing, but not at adult par, skill and experience growing, but not at adult par = less than adult performance and pay.

B The adult worker. Strength and endurance at maximum experience and skill near or at maximum = maximum performance and pay.

C The older worker. Physical strength and endurance receding, experience and skill at par = generally less than adult performance and therefore less pay.

I never could understand, I do not now understand how industry as such can practice charity. Monies so devoted must by necessity be deducted from wages, salaries and dividends to stockholders or else the cost added to the cost of the product, in which case the charity is given, to be sure, without their knowledge by the consumers of the industry's product. Some day man may achieve sufficient stoicism to face with equanimity the fact that charity and doles are for the children and the sick, not for the aged, unless incapacitated by age.

If what I so far said squares with facts, reason and wisdom as well as with our conception of justice, we might expect educational institutions to be ahead of industry in the elimination of waste of the older workers. But this is not so. In general there is full salary and duties of college and university men up to 65 or 70 and then abrupt unemployment or assumed total incapacity. Two factors are probably mainly responsible for this waste: (1) the younger generation in a hurry and (2) the older generation so ignorant of biology that it cannot see the justice of reduced pay for reduced capacity and performance. One of our large state universities recently recalled as dean of its graduate school a man now 77 whom the same university retired from that position nearly ten years ago. It is not probable that this university dean is today more capable than he was ten years ago. It seems more probable that this university wasted a valuable human resource for ten years.

According to the U. S. census, the number of people past 65 years of age in our population has increased during the last ninety years from 2.6 per cent to 6.8 per cent. If this trend continues, and I think this is assured by more of science and the better art in medicine, fifty years hence about fifteen out of every hundred people will be over 65 years old. I think we can add that, by and large, this army of older people fifty years hence will be even better qualified for useful work than are the people of the same age today. Thanks to more science and better art in today's medicine, our larger aged army of 1940 is less decrepit than was our smaller army of 65 year olds a hundred years ago. It is sheer waste, bad biology and gross injustice all around to feed, house and clothe this army in idleness. Old age pension is not the answer. The dole is not the answer. The only answer is useful work for pay, plus sickness and accident insurance. When aging has rendered us incapacitated for useful work we are truly sick, and sickness insurance should meet our needs. I think I am discussing important principles, not arguing about names, not fighting windmills. Still it must be admitted that at 68 some people fail to recognize their own delusions. I think that useful work is a privilege and a blessing, not a curse. It is also a biologic and social duty as long as we can carry on. Because the probability of less elastic arteries and less cardiac reserves, not to mention less strength in the skeletal muscles, the worker past 60 should, as a rule, not be put at tasks calling for the physical power that a worker aged 20 to 40 can deliver with safety. Moderation in all things, and a thorough medical check up twice a year will aid the older worker in keeping fit to carry on.

¹ Tuohy, E. L. Feeding the Aged. *J. A. M. A.* 121: 42 (Jan. 2) 1943.

There is the prevailing view that quitting useful work before the infirmities of old age and specific disease compel it hastens the age decline and brings on death sooner. It is difficult to check this view by adequate controls. So far as I know, this view is based on conspicuous instances forgetting the exceptions. But to the extent that idleness decreases the zest of living, and unhappiness and depressing mental states actually impair some of our body machinery, it may be true, especially if the pleasure from good food is still strong, for in that case injurious overeating is likely to become the rule. I dream of a tomorrow when our millions of men and women well past the chronologic three score will say, with Albert J. McCray, aged 71, now running a drill press at a Douglas Aircraft plant, "I'd rather have a job than a pension any time,"—for that spirit helps to keep the older worker young and aids in making America stronger.

5228 South Greenwood Avenue

PROCESSING TECHNIQUES IN PHYSICAL EXAMINATION

FRED B. WISHARD, M.D.

Medical Director, Delco Remy Division, General Motors Corporation
ANDERSON, IND.

The success of the American production system is dependent on many factors, of which two extremely important ones are (1) progression from one phase of assembly to the next and (2) elimination of repetitive operations. In a tour through a well organized industrial plant one is at once impressed with the fact that, while innumerable dissimilar operations are being done, an atmosphere of order pervades the whole with each step properly placed in sequence and essential to the completion of the finished product. This is necessary for two particular reasons: (1) the need for using available manpower to the best advantage and (2) the fact that waste motion (or material) represents an increased production cost which in a highly competitive market directly affects sales and profits. This is one essential difference between private industry and politically controlled or operated manufacturing units.

Although industrial medical practice has been a separate entity and a recognized specialty for many years, very little has been done until comparatively recently to improve its operating status—to streamline it to eliminate waste motion. During the past four or five years the duties of the plant physician have more than doubled. In many plants the physician has to pass on transfers, all changes of jobs and manufacturing processes which entail hazardous operations or the use of toxic materials, and he finds his time otherwise taken up in conferences and the like—all this in addition to what he used to consider his regular duties—emergency surgery, physical examinations and so on. Without organization he would never get his work done, he would either quit in disgust or suffer a nervous collapse.

Our own medical department was similar to the departments of the majority of industrial plants visited during the past few years. It had started out as a glorified stepchild of the employment office and had gradually expanded through the years to include radiography and other activities but was still only too

apparently in overgrown first aid station. When one considers the evolution of industrial medical practice, this is not at all difficult to understand. Originally, first aid was a necessary evil with some retired pensioner in charge. The fact that he had little if any knowledge of medicine or first aid training had no bearing on the matter. I very soon had its cigar box containing iodine and assorted bandages, while frequently certain workers acquired considerable renown for their skill in removing foreign bodies from eyes with toothpicks. So the first aid station came into being. Later on practical nurses and still later graduates were placed in charge under the supervision of some doctor who dropped in occasionally but never took it very seriously. Then came the full time plant physician who was willing enough but who had to prove his worth to management and who found it quite difficult to demonstrate the dollar value of intangibles. But gradually the scope of his activities increased until at the present time the ramifications of the medical department reach into all manufacturing departments and processes. At first there was very little order and less system. Applicants for employment reporting for physical examination, were conducted past employees being treated for wounds of all sorts, the odor of disinfectants permeated the air, and the impression on the candidate was that this must be a bloody place in which to work. It was always our luck to have a lot of accidents on days when hiring was heavy, so that the people coming in were certain to see us at our best—or worst.

There were other problems also, one being that of department layout. The nurses were constantly walking from one end of the place to the other, so that an eight hour tour of duty resolved itself into a sort of "bumon derby." Patients were received in one room and taken down a long hall to the x-ray room, where they removed such articles of clothing as the nature of the examination required and then had to dress before being taken elsewhere for treatment or further examination. The use of the x-ray room for undressing and dressing prevented its being used for other purposes, so that it was only about 60 per cent efficient. After taking the picture, the technician had to carry the cassette a considerable distance to the darkroom for processing. She then had to take the wet film across a hall to the view box. Later returning the film to the darkroom for drying. If the doctor wished to see some one particular film, the technician had to wait until others in course of development were sufficiently processed to permit her to turn the light on or open the darkroom door. These were minor delays, yes, but in the aggregate entirely too much time was wasted, and when production schedules are up and the plants want their help delay means the loss of a lot of production dollars, the ill will of the foreman and supervisors who want to know why they haven't gotten their men and criticism of the personnel-medical setup, until tempers get badly frayed and we say things we really shouldn't.

Another problem was that of individual rather than collective examinations. When several men are stripped in one large room they resent the lack of privacy. While curtained booths help somewhat they do not fully solve the problem. A solid door has a certain psychologic value, even though there may be others on the other side, the closed door insures privacy.

These are only a few of the problems with which we had to contend. Through the years we had given the matter considerable thought and we recognized that it

we were willing to break with tradition our production system had many features which were applicable to our own problems, such as elimination of repetitive motions, standardization of technic and other features which would increase our efficiency.

In planning our layout, the first step was to classify our contacts into one of three main groups:

1. Preemployment physical examinations
2. Employees who had been off sick reporting back for duty
3. Employees on company time reporting for treatment examination or consultation

Groups 1 and 2, i.e., those undergoing preemployment physical examinations and those returning to work following absence from all causes, should not come in contact with group 3, employees undergoing treatment or examination nor should those in group 3 come in contact with groups 1 and 2. To accomplish this two waiting rooms would be required, so situated that a man coming from the shop would not get into the applicant's waiting room, which communicated with the employment office and an outside factory entrance, nor should a prospective employee be able to get into the factory proper. This was quite important, for in times past applicants or those off duty would frequently be found wandering through the production departments. The most strict inspection at the factory gates would be futile if this by-pass existed.

It had long been our routine practice to take x-ray films in all cases of injury to bones and joints, no matter how presumably trivial the injury appeared to be. Although this necessitated quite a bit of extra work, experience has shown that it was fully justified. In addition, all applicants for employment, as well as those returning from sick leave, have chest films taken, also a film of bone or joint injury sustained in recent automobile accidents or the like. We felt that it would be better to have one radiographic unit of superior quality with a centrally located processing room than to install two units and divide our activities and records. In order that the x-ray equipment might be equally accessible to the two groups (old and new employees) we decided to locate this room first and arrange the other activities around it. In laying out a medical department one should dismiss any idea of remodeling, as such, lest the completed job be no better than before. The fact that a certain unit such as the first aid, or a waiting room always had been in this corner or that does not necessarily mean that it was most efficient in that location.

As all our plants are conveniently situated with reference to an excellent general hospital, we have never attempted to keep any patients overnight or perform any surgery in our plant setup, which is essentially a minor dressing station and examination and consultation center. Many years ago Dr. Allen B. Knavel of Chicago educated us to the fact that tendon suturing and repair of traumatized extremities merited greater care than that afforded by kitchen table technic. By referring our surgical work to the city hospital our main planning problem was that of examination and consultation with dressings and treatment playing a secondary role. We therefore broke down the entire procedure of physical examination of applicants into individual steps, which we arranged in sequence. It began with his reception in the applicant's waiting room, where he was given a physical examination card and conducted into the preliminary examination room.

Presuming that a complete examination, including photograph, finger prints, chest x-ray and physical inspection takes thirty minutes, if the examining physician interested himself in each step of the procedure he could pass on only some sixteen applicants during an eight hour day. But if he delegates the bulk of these duties to others and confines himself solely to a review of the x-ray film and inspection of the candidate, he can handle from twelve to fifteen per hour, i.e. one hundred and twenty or more per day. Furthermore, a clever nurse can do many of these minor tasks far more quickly and efficiently than the doctor himself. In the matter of drawing blood specimens for serologic examinations we have several nurses who are extremely adroit at hitting veins and draw a hundred or more specimens of blood a day as a matter of course. Our x-ray technician and her assistant are both graduate nurses interested in radiology. To them a hundred or more chest films are a normal day's run, with the last as technically perfect as the first. This is very important, for aside from the diagnostic value of a well taken and properly processed film there is a medico-legal angle, we might have to display some one film in court in the event of a damage suit, and nothing is more embarrassing than to attempt to defend a case by presenting inferior films, besides, it takes no more time and but little more effort to take a good picture than a poor one. For fingerprinting and photography we trained two young women from our office staff.

The functioning of the preliminary examination room is under the supervision of the nurse who draws the bloods. It is her duty to see that things go smoothly, that applicants are admitted promptly, treated politely and passed on to the x-ray department. The average applicant is frequently a bit confused and apprehensive. If he is made to wait any great length of time, is greeted in a brusque manner or is treated roughly, he at once gains an unfavorable impression of the medical department and of the corporation which it represents, for quite frequently the only contacts an employee has with management are his foreman and the doctor. If we start a man off right we seldom have much trouble with him later.

We first take his photograph for identification purposes using a 35 mm camera at 30 inches, $\frac{1}{25}$ second exposure at f/4.5, with one number 2 Photoflood bulb in a reflector. He is seated at the photograph table which was carefully designed for that purpose. His name, Social Security number and the date, together with 'Delco Remy, G. M.' are arranged on a "bulletin board" which is placed in position before him. The finished film shows these data below the picture of the person himself. All data are carefully checked, particularly the social security number, so that no mistake will be made. Having his picture taken by an attractive young woman makes him feel better, and he is then ready for his finger prints. This done, he is stretched out on a cot and a blood specimen drawn by the nurse before he has time to become alarmed. Further, very few men, or women either, will argue with a woman, which they might and probably would do if a man was to be drawing bloods, so that to date we have had practically no refusals in some 9,000 cases. Occasionally some man faints (no women to date) and for that reason we always have them lie on a cot, for if a man faints and falls to the floor he might injure himself seriously, and even if he does not, a 200 pound man on the floor is somewhat of a problem to the attendants.

Points to consider

1 Drawing a specimen of blood makes many persons nervous and they do not finger print or photograph well afterward.

2 To roll up his sleeve, the applicant must remove his coat or sweater. He then has to put the garment back on before being photographed.

3 When he lies down for his blood test he musses his hair and collar and then has to primp a while before having his picture taken, all of which takes time.

We therefore take the picture first and then the finger prints. Finally we draw the blood specimen. When this is done the applicant is conducted to the disrobing booth and does not need to pause to rearrange his hair or put on his sweater or coat. At the door of the disrobing booth the nurse instructs him to strip to the waist and slip on the poncho-like gown which he will find in the booth. The nurse takes him to the booth rather than an ununiformed attendant, as it gives this step a more professional tone, particularly the instructions relative to disrobing. His examination card is placed in a rack on the x-ray room door and a signal given to the x-ray nurse, who goes to the booth and escorts the man across a narrow hall to the x-ray room, where his chest film is taken. An observant person can be of great value at this point. Our technicians, being graduate nurses, make a quick survey of the man's general appearance—rash or other skin disorders, deformities of the thorax and arms, spinal curvature and many other things. She at once informs the examiner by means of our interdepartmental phone system. He comes to the x-ray room and may suggest other films, such as a lateral view of the spine or a film of the hip or other part. The examiner would doubtless pick up these things in the course of his inspection later, but that would necessitate the man returning to the x-ray room, instruction of the technician as to what was desired, and considerable time lost. Our x-ray technicians have seen so many skin cases that they can diagnose secondary syphilis and other undesirable conditions at a glance. The chest film having been taken, the man resumes his gown and is escorted back to his booth by the technician, who directs him to remove the rest of his clothes, lock the booth door from the inside and await the examiner. She then flashes a light which is seen in the examining room, takes the examination card to the examining room rack, returns to the x-ray room and hands the cassette containing the exposed film to her assistant. She is now ready for the next one. The assistant immediately starts processing the film in a temperature controlled tank. We use standard Eastman x-ray developer and hypo at from 65 to 69 F for five minutes developing, five minutes fixing in the hypo. We do not use "refresher" chemicals. After seventy-five, 14 by 17 films or their equivalent are run through, the tanks are drained, cleaned and supplied with fresh solution. Since we take about that number of films daily as a routine, the solutions are changed every day, and if the run is particularly heavy we may pause in the middle of the afternoon to change our solutions. At first thought this might appear to be wasteful, but we do not feel it to be so, for a good film used in evidence can, and in several instances has, saved enough to buy a lot of chemicals.

Within ten minutes from the actual taking of the film it is ready to be viewed by the examiner. The

doctor notes the signal over the dressing booth door goes to the rack and, taking the examination card left there by the x-ray technician, calls for the man by name, asking him to step out into the main examination room. The man steps out and goes immediately to the scales, where he is weighed and his height noted. The matter of weight is of considerable importance. Most men, particularly light weight ones, list their poundage at more than it really is. A month or so later, particularly if they don't like their job or the shift they report back, complaining of loss of weight as evidence of an inability to eat, general nervousness and the like. We frequently find that many who think they are losing have actually gained in weight, so that they are not suffering as much as they think they are. This is particularly true of men on the night shifts who want to be transferred to days, or foundry men who want jobs in other departments. We might have had weight and height recorded in the preliminary examination room but felt that it would be better to include it in the course of the physical examination, with the man stripped.

The examiner then takes a short history. We do not rely to any great degree on a history given at time of employment, for the average man in search of a job will often very conveniently forget various items which might be of more than passing interest. If there are any objective signs, such as operative scars or deformities, note is made of them. The blood pressure is then taken. While most younger persons will have a normal pressure or even a hypotension, occasionally we find one with a pronounced hypertension, sufficiently often to justify taking a reading on all. The heart sounds are noted by means of a stethoscope for murmurs, arrhythmia, extrasystole and so on. No effort is made to get breath sounds. The examiner then goes to the grid which separates the two through the wall view boxes and calls through the grid, which is light proof but transmits sound, to the technician in the x-ray processing room and asks for the film whose number was written on the examination card by the technician who took the chest film. All films have a number photographed into the corner as a matter of permanent record. The technician then places that particular film in the view box, closes her side and turns the handle. The examiner can then open his side, the box becomes illuminated and the film is at hand for inspection in the presence of the applicant who is usually quite interested and joins the examiner in viewing it. If there is any pathologic condition present, this is the proper moment to discuss it with the applicant. It has been our practice to take a flat film of every one and, when any pathologic condition is observed, return the man to the x-ray room for a stereoscopic series of his chest. We do this in all cases even though there may be sufficient pathologic change present to justify rejection such as presumably active pulmonary tuberculosis, as we feel that we can learn enough from stereoscopic films of any one particular case to more than compensate us for the expense incurred. By this practice we have built up quite a considerable library of stereoscopic films of about every sort of pulmonary disease from "Wheaten" to carcinoma (of which we have 3 cases of primary carcinoma of the lung).

Presuming that everything is all right so far, we next test the applicant's vision. In times past we were constantly misplacing our reading chart (we test for

close vision only, on the theory that if a man can see to read he can see distant objects sufficiently clearly to satisfy our demands), so we arranged to have our examination cards printed with a type which, when held at 20 inches distance indicated a 20/20 vision. Therefore, if the man can read the type on the examination card he has a normal reading vision. In the event that he fails with either eye he is then tested by means of a stereoscopic eye testing apparatus which gives his visual factor for each eye and is so designed that it is quite impossible to cheat even if he was so inclined, which of course he would not be. By means of this machine we can evaluate his vision within one or two minutes and check him for stereopsis, color blindness and other conditions. The examiner then tests his knee jerks, elbows and so on, palpates his abdomen, has him stand up and checks him for hernia, has him walk about a bit to observe his gait and survey him generally, and if nothing else is noted the inspection is over and the applicant returns to his booth to resume his clothing. Items noted are recorded on the examination card and the applicant is ready to return to the personnel office for assignment to his job, and the examiner calls for another one. In all, this part of the examination took from five to seven minutes, frequently less, sometimes more particularly in the case of rejections when the examiner discusses the matter at considerable length with the applicant, explaining just why he cannot be taken on and if some disease condition is present tuberculosis and the like arranges for an appointment with the man's personal physician and otherwise manifests some personal interest in the man's condition. We do not subscribe to the practice of rejecting a man and saying nothing about it—passing the buck to some one else to break the bad news to him.

It will be noted that at no time has the applicant come in contact with the other activities of the department. When he has dressed and walks out of the disrobing booth and through the short hall with which it communicates, he finds himself in the personnel waiting room—there is no other place for him to go. He cannot get out into the shop until he is officially taken there by a guide. Nor as stated before, can an old employee with a bandaged arm or leg stumble into the examining unit to disturb the new applicants.

The outer door of the examining room opens into the first aid section, so that an employee coming in from the shop can be admitted to the examination room direct without passing through the outer maze. If he is to disrobe, he can enter a booth to do so and later on pass out into the first aid section and thence to his job.

The x-ray room likewise has two doors, one for applicants from the booths and the other opening into a hall adjacent to the first aid section. An employee can thus be admitted to the x-ray room via the first aid section and then wait in a booth located across from the x-ray room while the film is being developed. This film can be viewed in the view box through the wall in the manner described before or if it is a follow-up film it is taken to the battery of view boxes, previous films are gotten out and comparisons are made. As occasionally happens an employee may have been sufficiently wounded to indicate hospitalization. All such men are removed by ambulance as we feel that any one sufficiently hurt to justify hospitalization suffers less shock when taken away in an ambulance than would be the case if he was to walk out to a car and

be driven over. With this in mind an entry was arranged through the back end of the medical department, so that a stretcher can be brought directly into the x-ray room and the man removed without being observed by others in the first aid section, and certainly not by any applicants for employment.

COMMENT

The examination layout described has more than doubled the efficiency of our examination procedure. It keeps applicants for employment from coming in contact with the other activities of the department.

CRITERIA FOR THE EVALUATION OF NUTRITION EXPERIENCE IN INDUSTRY

FRANKLIN C. BING, PH.D.
CHICAGO

Much has been written and spoken about the advantages of an improved nutritional status, and it is not surprising therefore that employers and workmen alike are eager to apply the facts of this branch of medical science as an aid to production in the war effort. Many conflicting statements are made and it is difficult at times to separate established facts from unestablished claims. If one could believe all the statements which one reads or hears, especially from organizations that have something to sell, but not limited to that field, it might be thought that the taking of vitamin capsules would speed up production or that the eating of candy bars would prevent industrial fatigue and reduce the rate of accidents. Just recently there came to attention a report to the effect that eating doughnuts between meals would reduce absenteeism. Manufacturers are being importuned to give their workmen chewing gum which contains ascorbic acid, or gum drops which contain salt, dextrose and ascorbic acid and which are said to prevent cramps, yield quick energy and serve as a preventive against certain industrial hazards. Unusual food preparations in the form of wafers or crackers reputed to be palatable and fortified with a number of vitamins and with inorganic salts have been represented as a convenient and sure means of improving the diet. Before accepting the claims which have been advanced for each of these and other similar products it would be well to ask where the evidence is. Are the conclusions supported by adequate scientific data? Do the representations have the approval of the several scientific bodies that have been established for the purpose of providing unbiased scientific and medical opinion of newer developments in this field?

From the scientific point of view there are two aspects to the problem of nutrition in industry: the determination of new facts through research on the effect of specific nutrients or groups of nutrients on the health and productivity of workers and the application of known principles of diet to the special population group represented by the employees of a war industry. It is my purpose in the present report to mention some of the criteria that will help evaluate the experience of others and that might be helpful to the industrial physician who is considering undertaking an investigation or a nutritional program in an industrial plant.

REQUIREMENTS FOR A SATISFACTORY RESEARCH PROGRAM ON NUTRITION IN INDUSTRY

The requirements for a satisfactory experiment on any aspect of nutrition in industry do not differ from those that apply to other investigations on human beings. First of all, no research should be undertaken except by a competent investigator. No better description of the ideal qualified investigator has been provided than that written by Karsner and Goldblatt.¹ According to their view a competent investigator is a person "who by training, experience, initiative, imagination, controlled curiosity and intellectual honesty is qualified to undertake an objective examination of the matter in hand without preconceived ideas or prejudice. He must attack the problem calmly, deliberately, with a clear program based on a well conceived hypothesis, and be thoroughly familiar with the work of others along the same and similar lines." Of course it goes without saying that such a person must be supplied with the materials and the equipment necessary for the problem to be studied.

It is regrettable that some investigations of the effects of the administration of vitamins or other ingredients of food have been made without sufficient attention having been given to the diet of the subjects. It is only by appraisal of the diet that a suitable experiment on human nutrition can be formulated. Workmen may be living in an unusual environment for many hours of the day and the question arises whether the dietary requirements might not be greater than normal for these persons. Only a careful evaluation of the diet on which these subjects are living will enable one to interpret the results of an investigation in general terms. With greater use of older workers, as discussed by Carlson,² there is the question of requirements for special age groups. Worthwhile studies can be made without giving special attention to the diet, particularly if there is made a thorough physical examination with the aid of some of the newer methods, developed particularly by Kruse,³ but the field is limited and the results may not be susceptible of general application unless the diet of the subjects is appraised or controlled.

A dietary survey provides only an indication of the probable nutritional status of the workers in terms of some standard. At best the dietary survey is difficult to carry out and equally difficult to interpret. Huencmann and Turner⁴ have found considerable discrepancy between dietary intakes computed first according to diet histories obtained by questioning the patient and, secondly, according to diet records obtained by weighing all portions of foods eaten over periods of ten to fourteen days repeated every three or four months for a year. The diet record of course is more accurate, but it repeatedly has been shown that even the diet record does not give a true picture if the contribution of each food is estimated from diet tables rather than from analysis of the foods that are eaten. For accurate metabolic data both diet histories and diet records are inadequate, but for purposes of showing the nature of the foods consumed and indicating where possible deficiencies exist the dietary study is invaluable and should be considered as a prerequisite for any suitable investigation of the nutritional problems of industry.

3 Kruse H. D. *Medical Evaluation of Nutritional Status*. J. A. M. A. 121: 584-591 (Feb. 20) 1943. Kruse H. D., Palmer, C. E., Schmidt, W. and Wiehl, Dorothy G. *Medical Evaluation of Nutritional Status*. Milbank Mem. Fund Quart. 18: 257-298 (July) 1940.

4 Huencmann, Ruth L. and Turner, Dorothea. *Methods of Dietary Investigation*. J. Am. Dietet. A. 18: 562-568 (Sept.) 1942.

There is a difference between dietary adequacy and nutritional adequacy. The first involves an evaluation of the foods consumed and the second a medical evaluation of the nutritional status of the patient. Many tests of physical fitness and of nutritional adequacy have been devised, and there is still a need for improvement through simplification of methods. In some of the more elaborate programs of research there are described a considerable number of physical, microscopic, roentgenologic, chemical and physiologic procedures. Not all of these tests have been thoroughly developed and applied, and certainly not all of them are needed in the appraisal of the nutritional status of workmen in order to make a satisfactory investigation in this field. Some of the equipment, such as the bion microscope and the slit lamp, may be difficult to secure at the present time. The important point is that the measures of nutritional status should be objective wherever possible and adequate for the purposes of the investigation. Well trained investigators prefer to have records of objective tests interpreted by a colleague who makes his readings without knowledge of the treatment which the patient has received. This method of controlling the preconceived ideas and prejudices of the investigator who after all is simply another human being is to be highly recommended.

A properly planned experiment involves the establishment of suitable controls. For every group of treated men there should be an equal number of men who are untreated. It is preferable that the treatment should be done without the knowledge of the men and if possible without the knowledge of the investigators who are recording the results. This cannot always be done. If vitamin preparations are being studied, however it is a relatively simple matter to administer a placebo to the control group. Because of the psychologic factor in all experiments with human beings it is worth while to have still another group whose members receive neither the therapeutic agent nor the placebo. In that way one can measure both the physiologic effect of the preparation being administered and the psychologic effect of giving something from which the workman expects to receive benefit. Differences in response between control and experimental groups should be significant as shown by appropriate statistical methods. To this end it is helpful if the investigation can be made on large groups over long periods of time. The number of persons in each group and the length of time of the experiment depend on the nature of the problem.

Finally it should be pointed out that any unusual results should be received with caution until the experiments have been verified by other competent investigators in other places.

THE MEASURE OF EFFECTS

Current interest in studying the nutritional requirements of industrial workers is prompted in part by the desire to improve the nutritional status and presumably the health of the workman and partly by the desire to increase production for war purposes. Can improved nutrition lead to increased production, cut down spoilage, improve general efficiency, reduce absenteeism and diminish accidents? Many leaders in the field of nutrition believe that improvement in the nutritional status will do all of these things in time, but the criteria mentioned are measures of human performance which are influenced by many factors other than diet. The maintenance of adequate nutritional status is a health problem, and the effects of procedures for improved nutrition should be noted in the worker's body. Man has the

ability to do wonderful things even though he may not be in that condition often referred to as "buoyant health." The history of nations illustrates the ability of man to surpass his physical limitations. It therefore seems unfortunate to have the sole measure of any nutritional investigation one of these secondary effects. The physician and the medical investigator, it seems to me, had best devote their efforts and measurements to health matters and, while controlling the psychologic and other factors inherent in any study with human beings recognize that the measurement and interpretation of such phenomena are primarily the concern of workers in other fields.

PRESENT KNOWLEDGE

Just a year ago a combined committee of the Council on Foods and Nutrition and of the Council on Industrial Health gave consideration to the practice of indiscriminate administration of vitamin preparations to industrial workers.⁵ The decision was reached that this practice could not be approved because of lack of sufficient evidence to show that it was desirable from therapeutic nutritional or economic points of view. To date there has been nothing reported that has led the councils to revise those conclusions. It is understood that several well planned experiments on the effect of administration of vitamins now are in progress. Some of these investigations are very extensive and it will be interesting to apply the criteria already mentioned to the reports when they are published.

As other speakers at this symposium will point out, the problems of nutrition in industry are so varied and so interesting that they present a challenge to investigators. Since the industrial worker is a member of the general population, it is apparent that he reflects the general picture of nutritional deficiency reported to affect the various sections of the United States. While there is considerable discrepancy between the reported incidence of dietary deficiency and the incidence of nutritional inadequacy, based on the experience and records of physicians, it can still be concluded that the diets of many persons can be improved with probable benefit to health. The working man is likely to be better fed than other members of the family, but there is evidence that there is much room for improvement in the nutritional status of the wage earner. In a study of the diets of aircraft workers in southern California, Wiehl⁶ has found the choice of foods to be exceedingly poor. The amount of green or yellow vegetables and of citrus fruits or tomatoes, these two classes of foods being our chief contributors of vitamins A and C, were very low and the amount of milk consumed was less than that considered desirable. Taking as a criterion two thirds of the recommended dietary allowances of the Food and Nutrition Board, she found that the diets selected by these workers were deficient as follows: 14.8 per cent were low in vitamin A, 24.8 per cent in calcium, 43.2 per cent in riboflavin and 46.0 per cent in ascorbic acid. No doubt investigation would reveal a similar situation differing in nature and in degree among industrial workers in other parts of the country.

Under certain environmental conditions it is possible that there may be an enhanced requirement for one or more of the dietary factors. This is well known in the

case of some industries where men are subjected to high temperatures and where, in order to replace the salts lost in the sweat, sodium chloride is made available. Whether more of the water soluble vitamins is required under these circumstances still remains to be demonstrated. Some of the vitamins, especially thiamine and ascorbic acid, have been suggested as prophylactic aids for protection against some industrial poisons. Work on these problems is still in the experimental stage. In the meantime a word of caution should be added. Where workmen are subjected to toxic substances it is important to continue to apply principles of sanitation and hygiene that are already established and known to be of value.

DIETARY IMPROVEMENT

Although studies of an experimental nature might well be undertaken only by those who have the training, facilities and time to make a worthwhile contribution, it is still possible for every industrial plant to contribute to the national nutrition program. As other speakers on this symposium will bring out, help and advice are available from trained nutritionists in every section of the country. Lunchroom facilities usually can be improved and in them the employees can receive a practical demonstration of the principles of wise selection of foods. Educational material can be provided to help workmen and their families to guide their food selections along scientific lines. All medical scientists interested in nutrition confidently believe that improvement in our dietary habits is capable of yielding tremendous dividends in time to come. Good diet does not necessarily assure good health, but it is one of the factors involved in the maintenance of health, along with adequate rest, tranquility of mind and freedom from infection. Further, good diet is so easily secured in this country under ordinary circumstances, if one has the necessary knowledge, that it is a health factor every one should avail himself of. Minor changes in faulty dietary habits and slight adjustments in the selection of foods and meals are capable, if wisely done, of converting an inadequate diet to one that is entirely adequate, as judged by any standard.

Of all physicians the pediatrician no doubt understands diet and the resulting advantages best of all, probably because the requirements for growth are better understood than are the requirements for maintenance of the adult organism. To grow well the child must eat well and adequately. The flesh of the well nourished child is deposited in firm form on a well mineralized skeletal frame. The characteristic turgor of the muscles, the healthy appearance of the skin, the milk-blue color of the conjunctiva, the firm pink gums, teeth unaffected by dental caries, the tongue pink, uncoated and with well marked papillae and with regular margin, and the glossy appearance of the hair are some of the attributes that we all associate with the healthy well nourished child. The healthy child is a happy child. Something approaching the feeling of youthfulness should exist for the well nourished adult. Our criteria of health in adult life may be too crude to permit a proper classification of the better nourished from the ordinarily nourished person. The signs and symptoms of mild thiamine deficiency, for example, are vague but they appear to be real and they disappear on administration of thiamine to the deficient patient. Among the symptoms reported are a general lack of well being, easy fatigue, loss of efficiency in daily work, sleepiness, lethargy, lack of ambition, forgetfulness, constipation, poor appetite, irritability,

paresthesias and gastrointestinal disturbances. Perhaps symptoms such as these, to which all of us at some time or another are subjected, may be alleviated to a considerable degree by devoting more attention to the diet. It will require considerable time, however, and many additional properly conducted experiments, before we can appreciate the potentialities of giving more attention to the nutritional quality of the foods we eat. Meanwhile, in the difficult days ahead before this war is won, with a need to conserve food and dietary supplements such as vitamins, it is the duty of all of us to obtain the best possible diet that our food supply and our knowledge of dietary requirements will permit.

535 North Dearborn Street

IMMUNIZATION FOR INDUSTRIAL WORKERS

PROBLEMS OF ORGANIZATION AND ADMINISTRATION

LEVERETT D. BRISTOL, M.D., DR. P.H.

Health Director, American Telephone and Telegraph Company
NEW YORK

The curative and the preventive treatment of disease including all specific prophylactic measures are functions of the physician. These functions particularly those of immunization through the use of serums and vaccines have been carried on in the home, the doctor's office, the clinic or the hospital, in connection with private practice, and in clinics and health services associated with public schools, colleges, public health departments and other public agencies, including the various military branches of the government. As a result of rapid developments in the field of industrial health, and particularly as a wartime measure it is now necessary and desirable to give attention to these problems as they relate to the needs of the working population and to determine how best to organize and administer these preventive medical functions in industry.

To assist management and working forces, there are four professional groups that should be brought together in any well developed cooperative plan for the immunization of industrial workers, namely (a) private practitioners of medicine, (b) industrial physicians, (c) public health authorities and (d) industrial health committees of state and county medical societies.

The private physician must be considered the key person in any immunization program for industrial workers. Upward of 85 per cent of medical service to industry is supplied by private practitioners. So far as possible and feasible a worker should be referred to his own doctor for any immunization procedure which may be desired on a voluntary basis.

The industrial physician should function as a deputy health officer in practice if not in fact and should be keenly aware of all opportunities to suggest and promote generally accepted scientific methods for the specific prevention of disease. In those instances in which it seems desirable to have employees immunized by industrial physicians in plant medical departments, this should be done on the request or with the approval of the employee's own physician.

Local public health authorities in many communities make available necessary services for the protective immunization of the civilian population. The coopera-

tion of community public health clinics should be sought by industrial management for the immunization of employees in special emergencies or where the services of a private physician or an industrial physician are not available.

Industrial health committees of state and county medical societies are logical groups to render advisory leadership and should include in their programs suggested procedures for the immunization of workers in industry. This would make it possible to take into account the variable local conditions and needs as they exist in different communities and industries. These committees, as recommended by the Council on Industrial Health of the American Medical Association are made up of representatives of the groups just mentioned thus making possible a close, cooperative relationship in working out a local program.

In general, it may be assumed that the working population is a cross section of the community, many of whom as infants and as preschool and grade school children have had the benefit of protective immunization against various diseases through the services of private physicians or school and health department clinics. While the control of these diseases rests largely with the community health authorities in cooperation with private practitioners of medicine, industrial organizations may do much to assist the public agencies by including attention to and education on these subjects in their own industrial health program.

SMALLPOX VACCINATION

Although the incidence of smallpox is currently at a relatively low level there are still enough cases to serve as focal points for epidemics particularly at this time when military mobilization and industrial expansion lead to more than the normal number of changes of residence and place of work. It would seem desirable therefore, to continue our interest and efforts in smallpox vaccination.

ANTITYPHOID INOCULATION

Immunization against typhoid, being of a somewhat transitory nature is not practicable as a routine among employed groups. It should be promoted chiefly among workers whose occupation requires considerable travel and contact with an outdoor rural environment, where special hazards may exist in regard to questionable drinking water and food supplies. Agglutination tests among those previously immunized would serve as a check on the need for further protection.

IMMUNIZATION AGAINST TETANUS

In industry, tetanus always must be considered a potential complication of accidental wounds. For this reason any program of immunization for industrial workers must take into account the possible use of tetanus toxoid particularly for those whose work definitely involves the contamination of wounds with dirt or soil which may contain this bacillus or its spores. Some companies according to the nature of their work, have promoted the giving of tetanus antitoxin to employees as a first aid measure following all cases of accidental wounds, while others have advocated it only in suspected cases.

IMMUNIZATION AGAINST UPPER RESPIRATORY INFECTIONS

If and when the value of protective vaccines or serums against the diseases of the upper respiratory system, such as the common cold and influenza, becomes

is scientifically established and medically accepted as that of vaccination against smallpox, typhoid and tetanus, it will be early enough for industrial management and industrial physicians actively to promote and encourage such immunizations among workers. This statement is not intended to discourage well controlled experiments or demonstrations, particularly with newly developed products in the possible reduction of sickness absenteeism, lengthy disability and secondary complications and after-effects of colds or influenza

CURRENT NUTRITIONAL ACTIVITY IN INDUSTRY

A REVIEW AND APPRAISAL

GEORGE R. COWGILL, PH.D.

NEW HAVEN, CONN.

The topic assigned to me is obviously one that cannot be discussed in any thorough fashion in the brief time at my disposal. Therefore I shall attempt merely (a) to present briefly some of the important phases of the subject that must occur to any thoughtful student of the problem of improving the nutrition of industrial workers and (b) to cite some examples of what is being done in this field.

Interest in this problem is comparatively new. In view of this it is natural to find some controversy existing in many industrial circles concerning the need for giving it any attention. To many a busy industrialist the idea that he is somehow responsible for properly feeding his employees means paternalism of an extreme degree. If his particular industry presents to its workers special hazards for which an improved diet is a preventive or an insurance against poor health, he no doubt feels willing to do what is called for in the circumstances. If such an industrial hazard cannot be shown to exist in his plant, he feels justified in objecting to any request that he "do something." Conservatism on his part is readily understandable. On the other hand it is generally recognized that there now exists a large body of knowledge in the science of nutrition which is not being applied as it should be, and there are possibilities for its application in the field of industry. It is now known that the shortcomings of diet can operate to affect health not merely in perfectly obvious fashion but also in very subtle and unappreciated ways. Therefore, improvement of the diet of industrial workers can have an important bearing on problems of absenteeism and the like.

The war has focused our attention on food problems. It has been said that "food can win the war." As a result of announcements regarding food shortages, the need to eat less of this and more of that in order that the armed forces may have what they require, the rationing of foods and kindred topics, housewives are finding it important to know some of the fine points of the science of nutrition and its practical application, how properly to substitute one food for another, and a host of related practical questions. Workers in industrial plants represent a very considerable part of our population. Along with everybody else they find themselves tremendously interested in this matter of the good diet, but with them still another reason operates namely the importance of keeping well through proper

eating in order that they may do their special part in making the materials of war needed by the soldiers in the front lines and the sailors on the high seas. It is probably safe to say that as a result of this combination of circumstances and proper utilization of our resources, we should within the period of one year be able to do more in changing the food habits of our people for the better than we could accomplish in a decade or even a generation of peacetime. Industrial physicians should be interested in this for several reasons, not merely because of obvious disease of dietary origin that may occur in industry, but because, as a result of some current activities in industry, we are seeing hitherto unappreciated ways that industrial organizations can assist in solving what is really a problem of public education.

Current nutritional activities in industry present several categories of interest. Research is being conducted on many basic questions involving foods and special food factors. The data gained in these studies will do much to determine the validity of certain current practices and to indicate various possible lines of future action. For example, how good are the diets that given groups of workers select? Does the scientific evidence at hand indicate that the administration of polyvitamin preparations is a simple and desirable solution to the problem of improving and insuring the workers' health as far as that is related to diet? Are there any particular vitamins or other food factors that are especially important in certain industrial situations? Special attention is also being paid to the adequacy of plant facilities for feeding workers, to insure that they are under the supervision of persons competent in the science of nutrition and experienced in the application of that science. The basic problem of education of the worker and his family in matters concerning wise selection of food is now being attacked in many interesting ways. Let us consider briefly each of these current lines of activity bearing on our main theme.

NUTRITION OF INDUSTRIAL WORKER

The National Nutrition Conference held in Washington, D. C., during May 1941 had a section devoted to the problem of the nutrition of the industrial worker. In its report that section called attention to the lack of scientific knowledge on which to base answers to numerous questions that were being discussed in many quarters. Later the Committee on Nutrition in Industry¹ of the National Research Council reached the same conclusion. Before long an opportunity presented itself for a carefully planned and controlled investigation in a large airplane factory in southern California. This plant employs from 30,000 to 45,000 workers. The plan of study called for careful physical examination of a representative group numbering at least 1,000. The examination was to include use of some of the latest techniques believed to reveal early stages of vitamin deficiencies. Efforts were to be made to learn the dietary patterns of these workers and thus to evaluate their ordinary diets. The effects of the administration of vitamins were to be studied. The importance of examining the diets of such workers must be obvious. If the diets should prove to be good, then the effects of administration of vitamins might well prove to be negative. The final report of this investigation has yet to be written, and therefore I can discuss the study only in very general terms and advise you to be watch-

Read before the Fifth Annual Congress on Industrial Health, Chicago, Jan. 13, 1943.

From the Department of Physiological Chemistry, Yale University School of Medicine.

ing for the detailed report, which will be forthcoming sooner or later. It is possible to mention here something about the dietary habits of these particular workers because a report on this was published recently.² It appears that over half of the 1,100 workers studied did not get enough green and yellow vegetables, and nearly half ate too few citrus fruits and tomatoes. Almost all ate enough lean meat, but one third failed to get enough milk, and a fifth were low in eggs consumed. This proves particularly interesting because, according to the Stiebeling-Phipard³ study of 4,000 family dietaries collected in different sections of the country, the southern California area proved to be one of the best on account of its liberal supply of milk and milk products, citrus fruits, fresh colored vegetables and meats. Evidently it cannot be assumed that, just because an industrial plant is located in a region well favored as regards supply of the important classes of valuable foods, the industrial workers in that plant will therefore be well fed, using these terms in their best nutritional sense.

The National Research Council's Committee on Nutrition in Industry has appreciated the importance of conducting similar studies in industrial plants located in at least four different sections of the country, because food conditions and other pertinent factors may differ considerably in respective areas. It has not been easy to get such additional studies carried out, but efforts are being made along this line.

It is an interesting observation that women workers as a rule make poorer selections of foods than the men. This proved to be the case in plants manufacturing munitions in England in 1917 and was even mentioned in a paper entitled "Women's Work,"⁴ included in "Occupation and Health," an official publication of the International Labor Office.

Let it be added that women, although possessing a large amount of energy in reserve, tend to feed themselves less substantially than men do (consuming fancy foods of little nourishing values), and to restrict their nourishment in difficult economic circumstances.

Discussion of this point with various persons leads me to conclude that this may be true to an appreciable extent in this country even now, for reasons most interesting to contemplate. One suggestion is that women are notoriously prone to worry about gaining weight and the effect of this on their figure, among them the so-called Hollywood diet for reducing has many devotees. This means that they avoid foods rich in energy. Unless they are unusually careful when doing this they can easily develop dietary deficiencies. With more and more women going into industry these days it is evident that we have here a problem worthy of serious consideration. Obviously its main solution lies in education regarding foods and nutrition.

Another line of research related to our theme is the study of special industrial situations like the manufacture of trinitrotoluene and beta-naphthylamine, which may present interesting toxicities in workers exposed to these chemicals. Until recently it had been thought advantageous to give each worker with trinitrotoluene a quart of milk per daily shift. Although milk because of its high calcium content is of value in

combating the intestinal absorption of lead, this food according to Foulger,⁵ has no particular ability to detoxify trinitrotoluene or prevent its absorption. On the basis of experiments with guinea pigs it appears that large doses of ascorbic acid are required to prevent loss of body weight when trinitrotoluene is taken. Foulger states that "as a result of our laboratory work we recommended in September 1941 that all workers exposed to trinitrotoluene in our plants should receive at least 100 mg of vitamin C per day and 1 mg of vitamin B₁. This practice is being followed." Confirmatory observations made in Britain have recently been cited by Holmes.⁶ The evidence that vitamin B₁ is of value here does not seem to be as clearcut as that concerning the value of ascorbic acid. It seems evident that we have here an important line of research that needs to be followed further. Much of the work done thus far is inconclusive and therefore should be regarded as interesting and suggestive but not warranting dogmatic statements at the present time.

PLANT FACILITIES FOR FEEDING WORKERS

Another current nutritional activity in industry relates to the examination of plant facilities for feeding workers. Industrial physicians whose plants maintain cafeterias, dining rooms, canteen wagons or food dispensing machines can do much to advance this line of work. They can make certain that these facilities are under the immediate supervision of persons competent in the science of nutrition, particularly the application of that science. It has been learned that too often such facilities have been turned over to a concessionnaire whose chief objective is to operate them so as to show a profit. Extremely few of these concessionnaires have been found to know anything at all about relative food values. Their chief plan of action seems to be to "give the public what it wants." In one instance the plant's eating facilities were handled by an employee whose chief qualification for the job seemed to be that he could successfully feed a given large number of workers in a minimum time.

Observations have been made of what workers select when passing through the plant's cafeteria. Such observations indicate that approximately half of the workers are in need of special instruction on how to select foods wisely. This has led some plants to adopt subtle and indirect techniques by which to get employees to make good selections, such as, for example, offering at a slightly lower price a special plate called a "victory lunch." Such a plate furnishes several of the protective foods which, if offered separately, would probably not be selected voluntarily. In those plants that have been quite successful in this sort of thing investigation reveals that the planning or supervising committee almost always had on it at least one person whose specialty was salesmanship, and who therefore was given a chance to bring the arts of his specialty to bear on this food education problem. This suggests that the industrial physician who is just beginning an attack on this problem in his plant will do well to establish a committee to help him and on this committee have representatives of the various interests, talents and responsibilities characteristic of his organization.

It is now possible to use in the plant's eating places enriched bread instead of the ordinary white bread. In the days ahead, when there will be shortages of

various common foods, it will probably be necessary to limit the number and variety of items offered, to do this properly will require the attention of some one trained in the science of nutrition. Under such conditions it should be possible to reduce the offerings to a relatively few extremely valuable foods, and employees will doubtless accept this limitation of choice because we are at war. To the extent that this situation is met by wise choice of items to be offered the nutrition of the employees in that plant will be improved accordingly.

The plant's eating facilities can be utilized to advantage in educating workers by the preparation and exhibition of good well selected meals. Demonstrations of this sort have an educational value that is difficult to overestimate. In Britain it has been found that such food demonstrations in the industrial canteens have a favorable effect on the worker and even on his wife, what the worker has experienced in the plant he demands in the home as well. What the worker has seen with his own eyes he remembers much better than what he has heard through his ears or read in a leaflet.

Other interesting points that might be mentioned here relate to the proper handling of food in its preparation for the ultimate consumer. It has been learned that many of the cooking methods in common use in restaurants, hotels, even hospitals, result in greater losses of nutritive values than are necessary. Many foods are first cooked and then kept on the hot table for from one-half to two hours, and such an additional period of heat has been found to result in losses. Cabbage, which is a good source of ascorbic acid when the leaves are fresh and uncut, so to speak, soon loses the vitamin when the leaves have been chopped up, thus exposing the cells to contact with air. The applications of such facts are obvious, but what is important here is that these applications too often are not being made. Competent nutritionists working under the supervision of the industrial physician and instructed to make the appropriate changes in methods of cooking and food handling can do much to remedy this situation and to make the plant's facilities for feeding workers do what is expected of them. Incidentally, it may be remarked that the physician who undertakes this line of work will acquire from his nutritionist quite an education in practical food matters.

EDUCATION IN FOOD AND NUTRITION

Underneath this question of improving the nutrition of industrial workers lies the fundamental problem of education in matters of food and nutrition. This education can be accomplished in part through efforts made by the plant itself and in part through general community, state and national effort. Let us analyze this briefly.

Activities at the community level naturally make the closest contact with the food consumer. At the county and state level the activities are more definitely of the coordinative, pooling of information and planning type. At the national level they are based on a view of the nation as a whole, the nation's relations to other countries, the special needs of the war effort, the balancing of national supply against national demand, the formulation of main policies that are in the interest of the nation as a whole, the implementation of these policies and coordination of them with activities at the state and community levels. Certain national activities, particularly those related to food advertising and the activi-

ties of industrial organizations which are interstate in character, do reach rather definitely the food consumer. This is well illustrated in many current nutritional activities dealing with this problem of education.

Many of our large industrial organizations have made valuable contributions in this connection. Concerns like Westinghouse Electric and Manufacturing Company, the General Electric Company and Servel, Inc. for example, in peacetime are manufacturers of household appliances such as refrigerators and electric stoves used for storing and cooking foods. Such firms have long had in their employ home economists and nutritionists trained to demonstrate these appliances, an activity that is educational in character. These concerns have devised ways of bringing to bear on the broad educational problem their trained personnel and other resources.

The first action taken was to educate their own employees and their families through carefully planned classes with demonstrations and the issuance of literature specially written for the purpose. The success attending such initial activities was so great that the material was soon made available to other firms. This led to the formulation of plans by which any industrial organization regardless of its size, can, if it wishes, now do something to educate its employees and their families by using material prepared by these several utility concerns. It is possible to establish "Health for Victory" clubs, a Westinghouse contribution, for which suitably written material is provided for the class leaders and all members. This particular scheme has developed to the point where any group of interested persons in a community can use it. Just as the National Red Cross will establish nutrition classes for any interested group, whether it is a mothers' club, a parent-teacher organization, a group of church women, a club of lodge members or the wives of members of a labor union, in the same way it is now possible to establish nutrition clubs using the teaching material furnished by the corporations just mentioned. In some cities, Chattanooga, Tenn., for example, the home economists of the utility manufacturer, the General Electric Company in this particular case, actually gave nutrition courses for the National Red Cross. In Chattanooga they conducted at one time five nutrition classes a week and taught a canteen class for the volunteer Red Cross canteen workers.

Approximately three hundred concerns have made or are making use of the material prepared by the Westinghouse Company for clubs, in some cases consisting of plant employees, in other cases made up of interested persons in the community in no way connected with particular concerns.

Servel Inc., has featured a plan that is particularly serviceable for the concern operating a cafeteria or similar facility. It also utilizes the local gas company and through it distributes teaching material to all interested parties.

In Peoria, Ill., the Caterpillar Tractor Company, through an interested plant physician has taken the lead in getting all firms in the city active in this educational work through the formation of such clubs as have just been mentioned and in other ways.

In Omaha the local program was primarily under the Civilian Defense organization assisted by a committee of the meat packing establishments. As part of the class demonstrations, samples of meat were donated by the local packers, and the Union Pacific

Company ran in the local papers full page advertisements of the community's educational campaign.

The Inland Steel Corporation has run its own employee classes, but these are under the management of the labor committees, so that in this case the activity might be called a labor project. The plant management makes facilities available and defrays the cost of the special teaching literature.

In some cities the direction and planning have originated in the community instead of in industrial concerns themselves. A good example of this is seen in the so called Bridgeport Plan, developed in Bridgeport, Conn. In this case the community committee, under the direction of a physician and his enthusiastic colleagues and assisted by the local gas company, felt that the logical approach to the problem was through the lunch box, and the community's campaign was worked out accordingly. As a result of the tremendous interest thus aroused, many of the local industrial plants became interested. They requested advice, which was gladly given on their feeding practices and programs. In pushing this community program there was developed the slogan "Pack A Lunch A Man Can Work On." Other slogans have come into the picture. As part of the Scovel collection of literature one finds cartoons featuring Hitler's face and the slogan "Eat To Beat The Devil." In Rockford Ill., the publicity of a campaign mentioned a "dynamite sandwich." This name apparently arose from a conversation two men had about a particularly valuable sandwich that was being exhibited. One man remarked that it certainly packed a lot, or words to that effect, his companion said "Yes! It's got dynamite." And so we now have the "dynamite sandwich," a term that a dry professor like myself would probably never have thought of in years but one which for a popular campaign does have its special appeal to many people for whom a special appeal of some sort is really needed.

These educational services developed by industrial organizations have concentrated on the most practical everyday problems that the food consumer faces. Technical material is always translated, so to speak, into common terms of simple well known foods and quantities, and illustrations are freely used. The material provided for nutrition clubs is remarkably complete. All that the teacher needs is given carefully outlined. No one can examine this literature without being impressed with the teaching skill and genuine salesmanship of things nutritional that have gone into its preparation.

At the beginning of this paper I mentioned the objection frequently encountered among industrialists to their firms undertaking any work dealing with the nutrition of their workers unless some industrial hazard preventable by diet or special dietary factors can be shown to exist in their given situations. In view of what has already been done by industrial units just as a contribution to our broad educational problem, and mentioned here only briefly, it seems to me that every interested industrial physician now has all that he needs to justify his firm finding some way to participate in this phase of current nutritional activity. This view receives added emphasis when one considers also the voluminous literature prepared by our government bureaus and agencies and readily procured from the agencies themselves the national nutrition office and various state and local committees. To the extent that a firm participates in this international effort through

any of the many ways open to it to that extent it can be sure that its employees have learned how to secure their own health through the proper use of food, and how they can help to win the war through the best possible use of our national food resources.

HOW TO GET ALONG WITH LESS HELP

LEGITIMATE SHORT CUTS TO ROUTINE SERVICE
CAN WE SECURE AND TRAIN TECHNICAL ASSISTANTS
FOR CERTAIN ROUTINE INDUSTRIAL
DIAGNOSTIC PROCEDURES?

EDWARD C. HOLMBLAD, M.D.
CHICAGO

In these wartimes, among the many problems confronting us in the practice of industrial medicine and surgery, is the necessity of doing more work in a shorter period of time with less help. The very rapid expansion of some of our industries has placed tremendous demands on the medical profession. Not only has the actual enlistment of trained industrial medical personnel depleted our forces but one of our sources of available medical personnel is almost completely gone. These are the young physicians and surgeons who have completed their internships and residencies and normally would be part time medical members in industry from two to five years or more. Practically all of these young men are taken into military service immediately on completion of their internships. Those available because they have been rejected from military service are very few, and even then more interesting or lucrative opportunities attract their services.

The necessity for devising short cuts is indicated by the number of persons per physician in industry as compared to civilian practice or even military service. We are informed that the usual personnel for a medical battalion is eight physicians, two dentists and from twenty to one hundred enlisted men who are responsible for a thousand or possibly twelve hundred persons. In industry these ratios are tremendously greater per physician, ranging all the way from two thousand to five thousand employees per physician. A hazardous war plant not so far away, where frequent periodic examinations should be done regularly, has six physicians for thirteen thousand employees, working three eight hour shifts and treating all the injuries as well as being responsible for the health of their workers and their preplacement examinations. Is it any wonder that some of these physicians are working fourteen to sixteen or even eighteen hours a day?

What legitimate short cuts may be devised in our routine services? First, I would say, is the necessity for adequate up to date equipment. Why should the industrial physician handicap himself with old or poorly functioning equipment? He should have the best of tools, adequate space conveniently designed examining rooms, dressing stations treatment and consultation rooms. Good light, adequate ventilation and pleasant surroundings and proper physical equipment are the least that industry should provide for their medical departments. Most of the larger industries have recognized this advantage, but I know of one large industry in this city doing about 75 per cent war work, expanded

to several times its usual enrolment, where the medical director has been trying to get new accommodations for his medical department for the past five or six years without success. The excuse that such equipment cannot be purchased because of war conditions is a mighty weak alibi.

Second, the industrial physician and surgeon should devise improved methods of treatment. Sets of rustless instruments with needles already threaded and placed in sterile packages can be run through a steam sterilizer at 20 pounds pressure for thirty minutes days in advance and kept available. When minor surgery presents itself, all that needs to be done is to open up the sterile towel and package and proceed immediately. In one plant the nurse had actually traced the exact size and shape of the enclosed needle on the outside of the package to save the doctor time in selecting a desirable sized needle and suture. Two 5, 10 and 20 cc syringes are likewise put up sterilized in advance, ready for immediate use. Eye spuds so sterilized in advance also are kept in small vials, the corks being inserted on removal from the sterilizer.

In a plant the other day I saw a nurse checking the vision by having the applicant start at the top and read down all the letters on the eye chart from 20/200 to 20/20. She could just as easily have skipped all the larger letters, being sure that the applicant was not cheating on the 20/20 line by substituting one or two different charts and have him read them backward as well as forward.

Third, simplified records are very definitely in order. Records where history questions and past medical history have to be answered Yes or No are very time consuming. This may be necessary to legalize a life insurance examination, but a simple check mark or zero can be made ever so much faster. A lot of the questions are not worth the time and space consumed in their asking or recording. Some insurance companies have simple medical blanks, others very complicated ones. Such a simple question as "For what period of time is he entitled to total disability?" saves answering a lot of unnecessary questions and places the responsibility on the integrity and honesty of the certifying physician, to whom it belongs in the first place. Did you ever stop to consider the amount of the negative findings recorded in the files of some of our larger medical departments and of just how much value these efforts are? One very practical director the other day pointed out that only abnormal or positive findings should be recorded, all others are assumed to be negative, something very worth while thinking about when you revise your forms next time.

Screening tests, whether they be x-ray films of the chest, blood pressure readings, urinalyses, pulse rates or weights, are of value only as far as they reliably portray positives or abnormalities in their findings.

Fourth, efforts should be made to avoid unnecessary preemployment examinations. During the first part of December 1942 a young man whom I examined boasted of having had six preemployment examinations in the preceding four months. He almost talked himself out of a job when I realized the wasted efforts of all those physicians' examinations of such an unstable employee shifting employment with the slightest whim or breeze. The rapid turnover in labor has been a serious problem in some medical departments. Recently one of the larger railroads found that by the time preemployment examinations cleared the general office almost two weeks after being done half had already left the

employment. They met this problem by allowing applicants to work two weeks without examination, and those that remained were examined at that time not ideal, but a practical way of handling this problem.

In some medical departments the preemployment examinations and periodic health examinations are being curtailed for the duration. It is pointed out that these applicants or reexaminees often purposely hide or cover up symptoms and maintain an attitude of "Here I am, a specimen in perfect health. Now try to find something wrong with me." The examiner has to go over him with a fine tooth comb to bring out a true appraisal of the man's condition. On the other hand when an employee has reported a sour stomach and abdominal pain several times, blood in his stools or recurrent persistent coughs and colds to the plant nurse or to the medical department such positive findings are of the greatest significance and warrant careful work-up, laboratory studies and diagnostic consultation—again an endeavor to apply our efforts and work to those who need it most, and where our efforts will be productive of the greatest results. Another group justifying reexamination are those returning to work after a period of three days or more of absence from work. Studies of these cases bring out interesting findings.

Fifth, many examiners are suggesting a simplified form of preplacement examinations. In reality they are inspections of physical appearance, functional tests of joint movements and the results of simple observations such as pulse, respiratory rates, temperature, blood pressure readings, vision and hearing tests. These are all simple procedures that can legitimately be done by any nurse under proper medical supervision. Only those with abnormal findings need be referred to the physician for study and decision. This also serves to eliminate one of the monotonous, fatiguing and exhausting phases of an industrial physician's work. What challenge is there to a physician's knowledge and eight or ten years of medical preparation to be doing routine preemployment examinations all day long? He is entitled to the joy and happiness in his work and the satisfaction of having accomplished something worth while.

TECHNICAL ASSISTANT FOR ROUTINE PROCEDURES

I have been asked to discuss the question "Can we secure and train technical assistants for certain routine industrial health procedures?" This, I would take it, goes beyond the graduate R.N. nurse assistant and brings up the question of certain duties and functions that can be delegated to persons with special training and qualifications but who have not had the advantage of a physician's or nurse's training. Let us first consider whether such are employed at present. I find that nearly all of our pathologic and clinical laboratory workers fall into this classification. Such medical technicians are doing blood counts, urinalyses, blood chemistry determinations, serologic and other types of laboratory work efficiently. Wise it is that their training should meet certain minimum standards and that schools training such technicians should meet an approved standard rating. One of the finest contributions to this field has been made by the American Society of Clinical Pathologists, which organized a registry of medical technicians in 1928. This registry has done much to raise and maintain the quality of the medical technicians. A statement made by Dr. Walter Simpson in 1933 is of the greatest significance as a guide in this field. The code of ethics of the American

Society of Clinical Pathologists demands that all registrants must agree to work at all times under the supervision of a qualified physician and that they shall under no circumstances on their own initiative render written or oral diagnoses, except so far as self evident in the report or to advise physicians or others in the treatment of disease."

There are other medical technicians that are recognized as auxiliary in the practice of medicine. Some of these are x-ray technicians, physical therapy technicians, occupational therapy technicians, hydrotherapy, dietetic, anesthetic and many other forms of medical technicians. Let us for a moment consider the technical assistants of an allied profession, namely dentistry. Almost every dentist has one or more full time assistants at his beck and call to assist in the routine work. These assistants only rarely have ever had any professional dental schooling and teaching. They are usually persons with a natural inclination to serve, assist learn to improve their accomplishments and incidentally get joy and happiness out of their work as well as an average living. Might we likewise give consideration to somewhat similar assistants, if and when the shortage of physicians and nurses makes this desirable and advisable? The training of medical secretaries and personnel for taking medical histories has already a good start in some localities. The taking of histories and notating of normal and abnormal physical findings are frequently routine functions of junior medical school students. The public as well as the medical profession has found that, when registered nurses are no longer available, practical nurses are frequently called in during an emergency. The important thing is that medical technicians in whatever field of endeavor they wish to become proficient should have the specialized training considered desirable. We have such lists of approved schools for chemical laboratory technicians, x-ray technicians, physical therapy and occupational therapy technicians. There are possibly others. Might it be possible to set up standards of training and instruction for medical technicians or technical aids to physicians and surgeons in industry? It is a field well worth exploring. I should think that the selection of such aids and technicians is most important. One would like to select those with qualities most likely to succeed in such an undertaking. Studies might be carried out to devise various types of aptitude tests and personnel and psychologic screening tests for the selection of those most likely to succeed. These workers are entitled to happiness and satisfaction in their work as well as a satisfactory living. I have had a most interesting and constructive communication from Mr. C. d'A. Gerken, director of personnel of Rochester Junior College, Rochester, Minn., who speaks with authority and the keen observation of a student pioneering in some of these personnel fields of study.

Now for a practical approach to this problem as to just what type of work and duties such technical aids and assistants might do. First, they must have adequate medical supervision at all times in all their work and must not diagnose nor treat ill or injured patients. They can be trained to take medical histories of illnesses and injuries competently for review by the examining physician. Heights, weights, simple inspections, color vision or urine tests, even respiratory and pulse rates might come within the scope of their endeavor. Individual capabilities and proficiencies will vary so much that the amount and type of work will have to be delegated to them by the responsible physician.

Around industrial medical departments are many such duties to be assigned to these technical physicians' and nurses' aids: maintaining of equipment, ordering, storing supplies, manufacturing or packing supplies. All the secretarial, clerical, recording and filing type of work falls into this category. Also there are certain types of health instruction, the chaperoning of women workers during examination by male physicians, the inspection of lunch rooms and inspection of general plant housekeeping, that can efficiently and properly be done by these workers.

With the safeguard and precaution that all their services be properly delegated and supervised by the responsible physicians and nurses, it seems to me that the judicious use of technical physicians' and nurses' aids offers the best solution for supplementing the shortage of physicians and nurses which has already occurred in some localities. As the war effort continues to expand taking more and more physicians and nurses, this shortage promises to become more acute in all industries and all localities.

28 East Jackson Boulevard

THE HEALTH AND SAFETY PROGRAM OF THE U. S. MARITIME COMMISSION

AND THE U. S. NAVY IN CONTRACT
SHIPYARDS

PHILIP DRINKER, CHIEF

Professor of Industrial Hygiene, Harvard School of Public Health
and Health Consultant to the U. S. Maritime Commission

BOSTON

The Maritime Commission and the Navy together now employ about 1 million workers, men and women, in contract shipyards. These yards do not include government navy yards such as those at Brooklyn, Norfolk and Mare Island. In the case of the Maritime Commission general policies emanate from Washington but the contract supervision comes from Maritime's regional directors at the four offices in Philadelphia, New Orleans, Oakland and Chicago. In the case of the Navy supervision emanates from the Supervisor of Ships in the Office of the Assistant Secretary of the Navy and then through the Navy's representatives at the yards themselves and in the appropriate Navy District offices.

In both cases contracts are let by the commission or by the Navy to private contractors. Methods used, general processes and the like are left to the contractor, the government keeping hands off except for inspections leading toward final approval and acceptance of the ships.

The size of the yards varies all the way from a few men to many thousands. Women gradually are getting more and more into shipyard work, the actual percentages, as one might guess, varying with localities. In general the day shift takes in something over half the total number of workers in each yard and the remainder are divided up between the second or swing shift and the third or graveyard shift.

Many of the yards, in fact most of them, have as little as 1 or 2 per cent of experienced men—men who have worked in shipyards before this war. Some of the

Read before the Fifth Annual Congress on Industrial Health, Chicago
Jan. 12, 1943

best yards that we have are built on made land in localities where ships never have been built before. Consequently, transportation and housing problems have been and often still are very serious.

Last summer the commission and the Navy appointed John M. Roche and myself as consultants on safety and health. A survey of selected yards around the country was made and a set of minimum standards for health and safety were evolved. These standards were presented before the various yards and the labor management groups and adopted on December 7 and 8 last at a conference held in Chicago. They will serve as our future guide for health and safety control in all the contract yards.

The Navy has assigned eight experienced officers to work with myself while Maritime has obtained the services of four safety engineers to work with Roche. These men will serve as consultants to all the contract yards throughout the country. Laboratories will be established on the East and West Coast as they are needed.

In general the health and safety problems confronting us are comparatively simple but because we have such an overwhelming percentage of green employees the task of carrying them out is not always easy. The pressure to turn out ships is great—it should be, for the need is urgent—and often we must condone practices that we would not accept in peacetime. We are glad to be able to say that both management and labor appreciate the situation and their cooperation has been most gratifying.

Eye flash burns and foreign bodies are among our most serious and most frequent causes of lost time. Obviously they are preventable but we are building ships in yards which often cover very large areas. Welding goes on everywhere, and it is very difficult to prevent flash burns of the welder's neighbor or even of an experienced welder who lifts up his welding shield momentarily and happens to be near another man who is welding.

Because of the general time and construction schedule it is common maritime practice to paint all metal surfaces as soon as possible with red lead. Generally this is done after the metal plates are in their final position, but some pieces are painted while in the yard. Welding painted surfaces into place presents a serious risk of lead poisoning, so that this practice has to be watched and the welder protected.

Similarly paint spraying which we do on a large scale, requires special protection for the sprayers and for the helpers and even for men in the immediate vicinity.

We propose to allow the use only of masks and respirators with Bureau of Mines approval. Heretofore there has been no control at all of the quality of protective equipment used in contract yards. It will be our job to see that such control now is put into effect.

In naval craft electric wiring is far more elaborate than on maritime freighters. Necessarily the Navy's wiring specifications demand better insulation than we need on freighters, so that it is common practice to protect these cables with insulators such as the fire resistant chlorinated naphthalenes and phenols. These may cause dermatitis unless proper precautions are

observed and we have met such troubles in some of the contract yards.

The rapidity with which all ships are built today is due in no small measure to the excellence of the construction planning. It would be impossible without arc welding, which can be seen today in all our large yards. Prefabrication of huge portions of the ships is the normal practice in all yards. Some of the jobs such as fore and after peaks and double bottoms, put the men in comparatively small spaces in which special ventilation is necessary to control welding fumes. All our health and safety consultants are prepared to advise the yards as to the adequacy of their ventilation and to make such air analyses as may be needed.

In general the medical and safety departments in the various yards are well organized and well run. We have been hit badly by the shortage of doctors in some districts, especially in rural communities, but probably we are no worse off than many other industries. We doubt if our situation in this respect presents any new problems.

Our work cannot be done as it should without preplacement physical examinations and occasional check-up examinations of men engaged in jobs potentially risky to themselves or to their fellow employees. Labor is apprehensive about physical examinations because of their occasional unintelligent use in the past. We are pledged to see that such examinations are done as they should be and that the results are used solely to help the men and thus to help us relieve the shortage in manpower. After all, our most valuable national asset is manpower. We believe we have the best there is, and our health and safety program is dedicated to its service.

THE NATIONAL NUTRITION PROGRAM FOR INDUSTRY

ROBERT S. GOODHART, M.D.

Technical Adviser on Nutrition in Industry, Nutrition Division,
Office of Defense Health and Welfare Services

WASHINGTON, D. C.

It is hardly necessary to recite to a group of this character the advantages which might reasonably be expected to accrue for one who is careful to maintain himself in an optimum state of nutrition. That not only the individual but the nation as a whole would derive benefit from a system which would insure each and all of us an adequate supply of foods to provide all our dietary essentials will also be accepted. I believe, without argument. Unfortunately the food situation in this country has never approached such an ideal state. Prior to the onset of the present war many millions of American people were not eating the minimum amounts of all the essential food factors needed to keep them in good health. In part economic factors were to blame, every dietary study or nutrition survey of population groups has clearly shown the greatest incidence of poor diets or of malnutrition to be in the economically poorest one third of the population. However economic factors have not been by any means, the sole determining forces, as evidenced by the fact that poor diets and malnutrition occur in all economic strata. Ignorance, food habits and prejudices and problems of supply have been responsible for a considerable proportion of the

malnutrition in the United States. The diets of war workers cited by the Committee on Nutrition in Industry in its report¹ and the results of the dietary studies on aircraft workers in California² nicely illustrate the roles played by ignorance and food habits.

In the California study, 56 per cent of 1,103 aircraft workers were found to ingest less than the recommended amounts³ of green or yellow vegetables, 49 per cent had 0 to 4 tomatoes or citrus fruits a week, 33 per cent had 0 to 5 glasses of milk a week, 0 to 1 egg was eaten by 23 per cent, while only 1 per cent consumed meat as infrequently as twice a week. For most of the men an increased consumption of milk and of citrus fruits, tomatoes and certain green vegetables would correct the major deficiencies of riboflavin, calcium and ascorbic acid and raise the intake of most other nutrients. It is of interest that 85 per cent of the diets furnished the recommended amounts⁴ or more of protein. This survey was made between November 1941 and February 1942. There is reason to believe that the supply of food to this region has deteriorated since then, particularly in relation to meat, milk and milk products, eggs, butter, tomatoes and canned goods.

Since the beginning of the war the problem of food supplies and distribution has achieved a position of paramount importance in practically every section of the country. Paradoxical as it may seem, this has tremendously increased the importance of the national nutrition program. No matter how efficient a distribution system may be set up or what efforts might be taken to stimulate farm production, it is most unlikely that we can continue to supply the armed forces and our allies with the foods which they must have, without bringing about some decided changes in the eating habits of the civilian population. Control of the production and distribution of foods is the responsibility of the Office of the Food Administrator. The prime function of the Nutrition Division of the Office of Defense Health and Welfare Services is, through the national nutrition program, the education of the American people so that every one will make the best possible use of available foodstuffs to meet his nutritional requirements. If morale is not to be adversely affected, changes in food habits necessitated by shortages of particular food items must be preceded and accompanied by effective nutrition propaganda showing that such changes in food habits are not detrimental to health and are often beneficial—that they need not detract from the joy of eating and that the government is doing everything within its power to insure an adequate diet for all of us.

It is particularly important that the nutritional status and the morale of war workers should not be adversely affected by food shortages, poorly prepared and poorly balanced meals and inadequate feeding facilities and eating conditions. The aim of the national nutrition program for industry is to prevent loss in war production through illness and dissatisfaction of war workers arising from poor dietary conditions and misunderstandings of food needs.

The nutrition in industry section is an integral part of the national nutrition program. It constitutes one of

the two major steps taken by the nutrition division of the Office of Defense Health and Welfare Services to tie the national nutrition program closely to the war effort. The other major step is the adaptation of the program to serve as a prime force in promoting willing acceptance of rationing and an equitable distribution of available foodstuffs compatible with the maintenance of good nutrition.

The nutrition in industry section functions mainly through the organization set up by the nutrition division for the implementation of the national nutrition program, i. e., through the eleven regional nutrition representatives and the state and local nutrition committees. Arrangements have been made for the appointment of an assistant nutrition representative for nutrition in industry in each region. It is probable that most if not all of the assistant representatives will have been appointed by February 1943. In the interim the regional representatives are attending to the industrial aspects of the nutrition program in their regions.

Approximately one third of the state nutrition committees have formed subcommittees on nutrition in industry. It is expected that the remainder will rapidly follow suit. The membership of the subcommittees on nutrition in industry quite generally includes representatives from health departments, and their industrial hygiene divisions, industry and industrial organizations, industrial physicians, labor, labor departments, food producers and merchants, caterers, service clubs and newspapers, in addition to nutritionists. Both the regional representatives and the assistant representatives of the nutrition division of the Office of Defense Health and Welfare Services are ex officio members of the nutrition committees and their subcommittees on nutrition in industry. The subcommittees are extremely useful, as they provide the nutrition committees with a direct contact with those groups in the state and community which are in a position to implement their recommendations. Such subcommittees are also frequently eminently qualified to define the needs of industries and war workers in their communities.

In addition to the organization set up for the national nutrition program, the nutrition in industry section of the nutrition division of the Office of Defense Health and Welfare Services has an arrangement with the Industrial Hygiene Division of the United States Public Health Service and the Ordnance branch of the United States Army whereby an inspection of meals, feeding conditions and requirements is to be included in industrial hygiene surveys of army ordnance plants. Reports prepared on nutritional conditions in army ordnance plants are transmitted through the industrial hygiene division of the U. S. Public Health Service to the army ordnance headquarters in Chicago as integral parts of the regular industrial hygiene reports. The regional nutrition representatives are requested to take whatever steps may be indicated to remedy community feeding problems about such ordnance plants.

Dr. Townsend, chief of the industrial hygiene division of the U. S. Public Health Service, has informed the nutrition division of the Office of Defense Health and Welfare Services of the close relationship which exists between his division and the various state industrial hygiene departments. As the "inplant" feeding problem logically belongs in the field of industrial hygiene, Dr. Townsend has requested that the state industrial

² Wiehl, Dorothy C. Diets of a Group of Aircraft Workers in Southern California. Milbank Memorial Fund, 40 Wall Street, New York.

³ Recommended Dietary Allowances. Committee on Food and Nutrition. National Research Council. Washington, D. C.

hygiene officers be kept informed of and be asked to participate in nutrition in industry programs within their states. This matter has been well taken care of by those state nutrition committees which have made the state industrial hygiene officers responsible members of the subcommittees on nutrition in industry.

At present, navy yards and shipyards under control of the Maritime Commission are contacted only on requests by individual yards. Such requests are handled through the regional nutritionists.

Many industrial feeding problems arise from or are aggravated by difficulties in transportation, inadequate housing, poor sanitation and inadequate community marketing and eating facilities, problems which are the direct concern of governmental bodies other than the nutrition division. The regional nutrition representatives are responsible for bringing such conditions to the attention of the regional director of the Office of Defense Health and Welfare Services when they adversely affect the nutritional status of the worker. The nutrition representatives are consulted by the representatives of other divisions of the Office of Defense Health and Welfare Services when any of the latter are contemplating procedures which may have nutritional implications.

No program of industrial nutrition can be complete without an effort to improve the eating habits of the worker in his home and his community. This can best be achieved by a system of adult education which recognizes the intimate and personal nature of food habits and is fully aware of the subtleties needed to inject a lesson of science into well established and cherished habits. Obviously the homemaker has to be approached and also the local caterers and storekeepers, with added problems as homemakers are drawn into industry.

It was realized early in our program that the prestige and cooperation of existing labor organizations must be solicited to make the nutrition message more acceptable. A National Labor Advisory Committee was set up representing unions within the Congress of Industrial Organizations, the American Federation of Labor, their respective auxiliaries and the Railroad Brotherhood. Our office is in constant touch with each representative regarding any matter within affiliated organizations.

Both the national Congress of Industrial Organizations and the American Federation of Labor organizations have dispatched messages to all their state and city organizations urging them to cooperate with the nutrition committees. Each labor group is urged to set up its own committee on nutrition, the chairman of which may function as a delegate to the local nutrition committee.

Possible functions of local labor nutrition committees are (1) to set up small nutrition committees in each plant to cooperate with the plant cafeteria management and with other implant activities, (2) to consider the feeding problems in the absence of cafeterias, (3) to exert an influence on proprietors of vending machines and neighborhood stores or stands, (4) to help the packed lunch campaign, (5) to pool information and popularize successful solutions, (6) to set up nutrition campaigns, demonstrations and courses at union meetings and obtain material, movies, advisers and leaders from local nutrition committees or other qualified sources

and (7) to harmonize these activities with sound attitudes toward the rationing situation, availability, shortages, alternatives and whatever else the food situation may require.

To assist this program we provide news and feature articles regularly to the labor press. The American Federation of Labor has a feature service supplying about 450 union papers. In addition, a special section on labor and food for war workers has been set up in the WPB labor press service which reaches 800 labor press editors weekly with 3,000 words on nutrition in industry.

Close relations have also been developed with the Association of Industrial Editors of employee publications. Our new service supplies 1,200 industrial magazine editors and many other industrial plants a variety of items each month for use in employee publications and on bulletin boards. Weekly releases are also sent to editors of women's pages of newspapers. All releases are sent in response to written requests and are distributed by OWI, the Office of War Information.

Biweekly releases to the victory letter, to *Victory* and to such government publications as *Consumer's Guide*, Department of Agriculture, and *Domestic Commerce*, Department of Commerce, are provided.

We gladly offer our services to industries such as Serval, Westinghouse and General Electric for the review of material to be included in the educational programs which they offer industrial plants. These programs are aimed at the industrial worker, his wife and his landlady and have valuable potentialities.

I have described in considerable detail the organization of the national nutrition program for industry on the federal level. However, this represents only part of the driving force of the program and a comparatively small fraction of the working organization. The great burden of the work is and must be borne by the state and local nutrition committees with their subcommittees on nutrition in industry. Theirs is the task of defining local problems and of formulating programs to meet local situations. They must be prepared to provide qualified instructors for nutrition classes and to give advice on plant feeding to industrial plants on request. It is to them that industrial and commercial caterers must turn for advice on nutrition. It is for them to decide which of the nutrition programs prepared by industrial concerns they can cooperate with in their communities. It is their responsibility to advise on posters, fliers, pamphlets and other educational material to be used in nutrition work in their communities. Last but not least, it is their function to obtain the cooperation of all sections of the community in the nutrition program. The nutrition division of the Office of Defense Health and Welfare Services with its regional representatives can advise, stimulate and guide the state organizations but, in the last analysis, the success of the national nutrition program for industry depends on the latter.

We know that states' nutrition organizations are qualified and willing to aid industry and labor in setting up and running effective nutrition programs. We strongly urge industry to call on the state and local nutrition committees for the services they are prepared to give.

malnutrition in the United States. The diets of war workers cited by the Committee on Nutrition in Industry in its report¹ and the results of the dietary studies on aircraft workers in California² nicely illustrate the roles played by ignorance and food habits.

In the California study, 56 per cent of 1,103 aircraft workers were found to ingest less than the recommended amounts³ of green or yellow vegetables, 49 per cent had 0 to 4 tomatoes or citrus fruits a week, 33 per cent had 0 to 5 glasses of milk a week, 0 to 1 egg was eaten by 23 per cent, while only 1 per cent consumed meat as infrequently as twice a week. ACUTE SODIUM FLUORIDE
POISONING

WILLIAM L. LIDBECK, M.D.

IRVIN B. HILL, M.D.

SALEM, ORE

AND

JOSEPH A. BLEMAN, M.D.

PORTLAND, ORE

The recent accidental ingestion of sodium fluoride at the Oregon State Hospital at Salem, Ore., resulted in the highest morbidity and mortality thus far reported in the medical literature from this particular poison. There were 263 cases, of which 47 terminated fatally following a meal of scrambled eggs. The identity of the poison was not established until approximately twenty-two hours had elapsed except that preliminary tests performed by Drs. F. R. Menne, N. A. David and H. J. Sears of the University of Oregon Medical School indicated a virulent poison in the stomach of some of the victims and in the scrambled eggs. When toxicologic examination revealed the presence of sodium fluoride, it was apparent that roach powder had been placed in the scrambled eggs served at the evening meal. Subsequent investigation disclosed that a patient helper had unwittingly mistaken roach powder for powdered milk and had added approximately 17 pounds of the compound to a 10 gallon mixture of scrambled eggs. Fortunately the eggs were not generally distributed throughout the hospital but were served to only five of the working wards.

CLINICAL FINDINGS

The food was rejected by many of the patients because of a salty or soapy taste, while others complained of numbness of the mouth. Extremely severe nausea, vomiting and diarrhea occurred abruptly and at times simultaneously, and blood was noted in the vomitus and stools in many instances. Soon after the meal there were complaints of abdominal burning and cramplike pains. General collapse developed in most instances but at variable periods of time, apparently depending on the concentration of the poison. This was characterized by pallor, weakness, absent or thready pulse, shallow unlabored respiration, weak heart tones, wet cold skin, cyanosis and equally dilated pupils. When this picture was pronounced death almost invariably occurred. Local or generalized urticaria occurred in some instances while in others there was a thick, mucoid discharge from the mouth and nose. When death was delayed, and in some cases in which recovery occurred, there were paralysis of the muscles of deglutition, carpopedal spasm and spasm of the extremities. Convulsions and abdominal tenderness and rigidity were absent. In the majority of cases death occurred between two and four hours after ingestion of the food, although in a few instances death was delayed for eighteen or twenty hours.

With the explosive occurrence of 263 acute and violent cases, amid inadequate surroundings, treatment was of necessity on an empiric basis. A teaspoon of salt and sodium bicarbonate in a glass of water served as a gastric lavage. Shock was combated with respira-

tory and cardiac stimulants, and the following were used alone or in combination, depending on the individual case: nikethamide, epinephrine, caffeine with sodium benzoate, neosynephrin subcutaneously, 50 per cent dextrose intravenously, whisky by mouth and external heat. Magnesium sulfate was used as a purge and was probably of more specific value than was appreciated at the time.

Through the office of the district attorney and the coroner examination of 6 bodies was authorized, and on 3 of these a complete autopsy was performed. The essential findings are grouped as follows. In the most acute deaths the mucosa of the stomach, duodenum and first portion of the jejunum was edematous and hyperemic. The stomach contents were mucinous and contained large amounts of undigested egg. The colon was empty except for portions of undigested food, indicating the fecocity of the diarrhea, the mucosa here was unchanged. There was a general increased wetness and acute congestion of the abdominal viscera, and the liver and kidneys were swollen. The lungs were ballooned at their edges, with occasional interlobar petechial hemorrhages. There was no aspiration of the stomach contents. The heart showed decided dilatation of the right chambers, which contained fluid blood. The brain revealed only slight edema and hyperemia. When death was delayed the only other changes consisted of petechial hemorrhages of the gastric and duodenal mucosa. In no case was increased fat noted in the liver. Microscopic examination of the various organs confirmed these gross findings.

TOXICOLOGIC EXAMINATION

The cooked eggs contained from 3.2 per cent to 13 per cent sodium fluoride in analyses made on different portions of the same sample indicating a spotted distribution of the poison. One patient dying fifteen minutes after ingestion of the eggs showed an estimated 17.2 Gm. of sodium fluoride present in the stomach contents, when death occurred one hour after ingestion of the eggs an estimated 3.7 Gm. of sodium fluoride remained in the stomach contents, when death was delayed four hours, the stomach was empty but the entire liver contained an estimated 0.85 Gm. of sodium fluoride and both kidneys an estimated 0.21 Gm. of sodium fluoride, when death was delayed for eighteen hours only 0.18 Gm. of sodium fluoride was found in the stomach contents. In all cases fluorides were easily identified by the etch test on glass from the ash in 10 Gm. samples of kidney and liver and by the presence of calcium fluoride bands on spectrographic analysis.

Roach powder contains anywhere from 30 to 90 per cent sodium fluoride depending on the manufacturer. The powder in question contained 90 per cent of the commercial salt. Sodium fluoride is a white powder with a salty, alkaline taste, odorless, very soluble in water and appearing grossly similar to sodium bicarbonate or flour. The fatal dose is given by Baldwin¹ as from 5 to 10 Gm. for human beings. This figure is the one most commonly accepted. Thienes² states that 0.25 Gm. has caused nausea and 4 Gm. has caused death.

The majority of reported poisonings by sodium fluoride have been mass poisonings due to the use of the compound in place of sodium bicarbonate, flour

Dr. Lidbeck is the director of the laboratory and Dr. Hill, assistant physician at the Oregon State Hospital. Dr. Beeman is a member of the Crime Detection Laboratory, Department of State Police, University of Oregon Medical School.

or epsom salt (magnesium sulfate) In Pittsburgh on Nov 11, 1940 sodium fluoride was mistaken for flour and added to pancakes at a Salvation Army service center, resulting in the poisoning of 40 persons and 12 deaths.³ Wirthlin⁴ reported a death by suicide following the ingestion of ½ pound of sodium fluoride in two hours Geiger⁵ reported 3 deaths when sodium fluoride was mixed with sodium bicarbonate, and in the same outbreak Carr⁶ reported 3 additional fatalities and 2 suicides Bell⁷ reported the recovery of 1 patient who was seriously stricken after ingesting an estimated 5½ grains (0.33 Gm) of sodium fluoride Maletz⁸ reported 1 case of fatal poisoning and 1 recovery, in which the amount of fluoride taken was small Sharkey and Simpson⁹ reported 1 case of fatal and 7 of nonfatal poisoning in which sodium fluoride was mistaken for epsom salt Their paper also contains an excellent review of the literature up to that time

COMMENT

The medical and nursing staff of the hospital found themselves confronted with an enormous task in caring for such a number of acutely ill patients The difficulty was further aggravated by the obscure nature of the poison which excluded the use of a specific antidote It is interesting to speculate as to the reasons underlying the severity of the reaction in the different cases On the basis of the toxicologic examination it is apparent that the sodium fluoride was unevenly mixed in the eggs, with consequent variation in the concentration It was also apparent that the older patients, because of their generally poor physical condition, withstood the effects of the poison less readily than younger ones The amount of food eaten naturally varied considerably, but it appeared that the more demented patients, who would be less discriminating in their food habits, suffered more than others When there was prompt and copious vomiting, the effects were less severe

Roach powder is commonly used around institutions, and our experience indicates that sodium fluoride is a more potent poison than has been generally recognized It would seem that the same precautions concerning the packaging, labeling and distribution of this compound should be taken as with other well known poisons That this danger is not apparent is indicated by the absence of a poison label on the container and failure of the manufacturer to color this substance so that it would be less easily mistaken for certain food substances to which it bears a close resemblance

THE ORAL USE OF SULFATHIAZOLE
AS A PROPHYLAXIS FOR
GONORRHEA

PRELIMINARY REPORT

CAPTAIN JAMES A LOVELESS
MEDICAL CORPS, ARMY OF THE UNITED STATES
AND

COLONEL WILLIAM DENTON
MEDICAL CORPS, ARMY OF THE UNITED STATES

Our purpose in this study is to determine whether the prophylactic administration of sulfathiazole prevents the development of gonorrhea The existence of an inordinately high gonorrhea rate among certain troops makes the development of an easily administered chemical prophylaxis particularly important The following incomplete experimental data are published as

*Veneral Disease Rates in Control and Sulfathiazole

a preliminary report because of the encouraging results already achieved

Jones¹ and Kline and Ryan² have published articles on the subject of sulfathiazole prophylaxis In both studies sulfathiazole was given in divided doses after exposure In the former study gonorrhea did not develop in any of 350 men who received sulfathiazole, in the latter, of 1,000 who received the drug 3 developed gonorrhea

METHOD OF STUDY

The test group consisted of a company of approximately 1,400 Negroes The control group consisted of approximately 4,000 Negro troops from the same post

The method of administering sulfathiazole was as follows All soldiers in the test group were required to "sign out" and "sign in" through the noncommissioned officer in charge of quarters On signing out, each soldier was given 2 Gm of sulfathiazole and was observed to swallow it in the presence of the noncommissioned officer During the first few weeks of the study all soldiers who did not have in their possession a copy of form 77 MD (station prophylaxis slip) on signing in were given 2 more Gm of sulfathiazole and an additional 2 Gm the following morning under the

Medical Slang—There is not sufficient distinction in the medical mind between the spoken and the written word Certain medical slang is highly descriptive and emotionally and intellectually suited to the purpose of professional discussion, when, however, such idiom is transferred to print it produces a different effect There are too many examples of words and phrases incorporated and accepted into the medical press which offend against rules of style and grammar Textbooks on the acute abdomen¹ are numerous disease may be acute, but an abdomen, never Exactness and dignity are the two essential qualities of good medical expression The surgeon who 'laparotomises' his patient and the physician who diagnoses 'P T B' achieve neither—The Decay of Medical Language, editorial, New Zealand M J 41 236 (Dec) 1942

same strict supervision. Later this exemption on the basis of station prophylaxis was discontinued and sulfathiazole was administered to all. Early in the course of the experiment restriction to the camp for a period of one week of those who received 6 Gm. was attempted in order to prevent overdosage. This restriction was later relaxed. The cost of this prophylaxis has been about 10 cents per soldier monthly.

RESULTS

The accompanying table presents the rates for gonorrhea, chancroid and syphilis of the test and control group from March through September. The administration of sulfathiazole to the test group was started on May 1.

It will be noted that in the control group there is no distinct trend of the rates for gonorrhea or syphilis. The rate for chancroid is considerably lower during the last four months of the total period.

Section 2 of the table includes all cases of venereal disease diagnosed during the period March through September. The decline in the gonorrhea rate is evident. Chancroid shows no clearest change, and syphilis remains constant except during the month of August, when a sharp decline is noted. Section 3 excludes those cases not under the influence of sulfathiazole when exposure occurred—men who were exposed away from the post while on overnight leave or furlough and who could therefore not obtain the additional sulfathiazole that would have been given could they have returned to the post. These cases are counted in section 2 as they were members of the group under study but are omitted from section 3 because of their failure to carry out the provisions of the study. One gonorrhea failure was noted in each of the months May, June, July and August. The situation is similar with chancroid infection. When sulfathiazole was taken according to the plan of the experiment, gonorrhea and chancroid almost entirely disappeared. Syphilis was unaffected, although the low rate noted in August is not explained.

SULFATHIAZOLE REACTIONS

No toxic or allergic reactions in the test group other than occasional complaints of mild nausea have been observed. No case has been hospitalized nor have any days been lost from duty as a result of the sulfathiazole administration. The possibility of sulfonamide sensitization has been considered, but there has not yet been an opportunity to investigate this problem. However, no indication of sensitivity has been observed thus far.

COMMENT

It is recognized that this presentation is preliminary in nature. However, it is believed that sufficient evidence is presented to prove that sulfathiazole prophylaxis will prevent gonorrhea and chancroid. It is our opinion that, under certain conditions and in a final form yet to be developed, prophylactic sulfathiazole administration would produce a remarkable decline in gonorrhea and chancroid in the Army. It is admitted that certain dangers are involved in administering this drug, particularly on a large scale and that the answer to certain questions has not yet been determined. In view of the magnitude of the venereal disease problem and its effect on man days, we believe that the risks are justified.

This experiment is being continued in an effort to simplify the administration of the drug and to obtain further corroborative data. Although no untoward reactions have been observed, no data are as yet avail-

able as to possible sensitization or other ill effects consequent on repeated administration of small doses. The study group is being observed carefully for such evidence. Until such data are available the study is not being extended, nor is it felt advisable that such measures be made routine practice.

SUMMARY

1. A company of approximately 1,400 Negro troops was given sulfathiazole prophylaxis of 2 Gm. before leaving the fort on pass. Those taking station prophylaxis received no further drug. All others received 4 additional Gm., 2 on returning to the fort and 2 the next morning.

2. In this company there has occurred a phenomenal disappearance of gonorrhea and chancroid. Excluding the failures not under the influence of the drug at the time of exposure, the gonorrhea rate dropped to a level of 8 per thousand yearly as compared with 171 per thousand in the control group, and the chancroid rate dropped to 6 as compared with 52.

CONCLUSIONS

1. Sulfathiazole administered orally appears to be an effective preventive against gonorrhea and chancroid.

2. Its administration in this experimental group has not been attended by serious reactions.

3. Sufficient evidence has been obtained to justify further extensive study of this problem.

Clinical Notes, Suggestions and New Instruments

Q FEVER

T. L. GENE ZIEGLER, M.D., Columbia, S. C.

The present war with its rapid means of transportation has focused our attention on diseases of far distant lands, some of which have never occurred in this country. The typhus fever group is of particular interest, and one should be ever on the alert for its appearance. McGraw's¹ classification is based on the insect vector and is divided into the epidemic and non-epidemic forms. The epidemic form is true typhus, the louse being the insect vector. Under the non-epidemic form are classified flea typhus or Brill's disease, tick typhus which includes Rocky Mountain spotted fever, Mountain tick fever and other mite typhus, sometimes called Japanese river fever or tropical typhus. In 1935 a new fever entity was first noted among the meat workers in Brisbane, Queensland, Australia. The cases reported were studied by Derrick² and Burnet³ and Freeman,⁴ who made their report in 1937. They described its clinical course and identified the causative organism as Rickettsia burneti. Although it has a certain resemblance to typhus fever, Q fever differs in that its clinical course is variable, there is no characteristic rash and the Weil-Felix reaction is negative. Recent investigations by Kendall,⁵ Bowen,⁶ Cox,⁶ Derrick⁷

3. Since this article was written data have been collected on 10 soldiers from the test group who were subsequently admitted to the Station Hospital for various illnesses. All had previously received sulfathiazole as a prophylaxis. Over an average period of six to five days each had taken an average of 45 Gm. of this drug. In the hospital, each patient received an average therapeutic total of 24 Gm. The individual prophylactic total ranged from 4 to 100 Gm. and the therapeutic total ranged from 5 to 52 Gm. Three of the 20 were treated with sulfathiazole powder or ointment. In this entire group a therapeutic response to the drug was satisfactory and there have been no reactions.

2. Derrick, E. H. Q Fever, a New Fever Entity. Clinical Features, Diagnosis and Laboratory Investigations. M. J. Australia 2: 281 (Aug. 21) 1937.

3. Burnet, F. M. and Freeman, Mavis. Experimental Studies on the Virus of Q Fever. M. J. Australia 2: 299-306 (Aug. 21) 1937.

4. Kendall, A. I. Australian Q Fever, Mountain Tick Virus and Pneumonia. Quart. Bull. Northwestern University M. School 15: 110-113, 1941.

5. Bowen, Albert. Acute Influenza Pneumonia. Am. J. Roentgenol. 34: 168 (Aug.) 1935.

6. Cox, H. R. Rickettsia Diaporica and American Q Fever. Am. J. Trop. Med. 20: 463-469 (July) 1940.

Burnet and Freeman,⁷ Dyer, Topping and Bengtson,⁸ Hornbrook and Nelson,⁹ and Dyer¹⁰ have shown a close relationship between Montana tick fever, pneumonitis and Australian and American Q fever. Etiologically they all agree that the rickettsial virus is the responsible organism and that the clinical variation may be due to different strains. Cox¹¹ suggested diaporica as the species of Rickettsia in American Q fever whereas it is the burneti in Australian Q fever. The insect vector in the former is *Dermacentor andersoni*¹² and in the latter *Hemaphysalis humerosa*.⁷

The bacteriologic, epidemiologic, cultural and serologic aspects of this rickettsial virus have been studied by Derrick,² Cox,¹³ Dyer,¹⁴ Davis and Cox,¹² Parker and Davis¹⁵ and Bengtson.¹⁶ The pathologic effects on the various organs of the mouse, guinea pig, rabbit and monkey have been demonstrated by Burnet and Freeman,³ Lillie, Perrin and Armstrong.¹⁷ Perrin and Bengtson,¹⁸ and Lillie.¹⁹ Dyer¹⁰ has shown a close similarity between Australian Q fever and a disease caused by an infectious agent isolated from ticks in Montana and also reported a case¹⁴ of human infection in a laboratory worker. Burnet and Freeman³ made a similar study and concluded that the virus of each of these diseases should be included in the same species. Hesdorffer and Duffalo²⁰ reported a probable case of American Q fever with a definite pneumonitis. A number of cases of atypical pneumonitis have been reported in which a serologic test was positive for the rickettsial virus. The clinical course of Q fever is variable which is due in all probability to the various strains of the rickettsial virus. Until the various strains have been properly identified it seems wise to separate the cases of Q fever with pneumonitis from those in which the clinical course is that of a true fever.

REPORT OF CASE

J A, a white girl aged 18 whose family history was negative and whose only illness besides the usual childhood diseases was acute catarrhal jaundice in November 1941, had the onset of her present illness one week after returning from the mountainous country of western North Carolina where she had visited in the country, drunk water from many sources and been on a number of hikes. Three days before the onset there was

general malaise, loss of appetite, constipation and an unwell feeling. The onset was dramatic and was ushered in with a hard chill and a temperature of 105 F on July 25, 1942. After three days of chills, fever, headache and generalized aching the patient was admitted to the Columbia Hospital. On admission the physical examination was entirely negative except for slight generalized tenderness in the lower part of the abdomen. Repeated examinations continued to be negative. A slight cough developed.

The fever together with the chills continued daily for two weeks. The chills were rather severe, during them she shook as if riding a rocking horse. The spleen was never palpable. A mild neuritis developed in the legs and feet and they became quite sensitive to touch. During the first week the highest daily temperature ranged from 105 to 105.8 F and never dropped to normal during the day. The temperature continued to reach 104 to 105.8 in the second week, 102 to 105.4 in the third week and 102.4 to 104.4 in the fourth week, dropping to normal once during the day. It gradually fell and became normal on the forty-sixth day, five days after she was given a blood transfusion. The pulse remained moderately slow and the lungs remained clear during the entire illness.

The laboratory findings were as follows. July 28, the hemoglobin content was 70 per cent, red blood cell count 3,500,000, white blood cell count 9,650 and the differential count polymorphonuclear leukocytes 68 per cent and lymphocytes 19 per cent. July 29, the white blood cells numbered 9,000 with polymorphonuclear leukocytes 78 per cent, lymphocytes 19 per cent, transitionals 3 per cent. August 6, hemoglobin was 71 per cent, red blood cell count 3,600,000, white blood cell count 7,100 with polymorphonuclear leukocytes 75 per cent, lymphocytes 25 per cent. August 17, hemoglobin was 65 per cent, red blood cell count 3,610,000, white blood cell count 5,200, with polymorphonuclear leukocytes 70 per cent and lymphocytes 27 per cent. August 20, hemoglobin was 67 per cent, red blood cell count 3,300,000, polymorphonuclear leukocytes 60 per cent and lymphocytes 40 per cent. The urinalysis showed a specific gravity of 1.016, was negative for sugar and showed 1 plus albumin and a few pus cells in the microscopic study. Repeated urinalyses were negative. August 11 a tuberculin test was negative. August 7 the stool culture was negative for the typhoid group. Blood cultures were negative on repeated examinations. Agglutination tests were as follows. July 31 typhoid positive in a dilution of 1:25, paratyphoid negative, *Brucella abortus* negative. Weil-Felix reaction positive in dilutions of 1:25 and 1:50. These tests were repeated on August 4 and 8 and all gave entirely negative results. A sample of the blood was sent to the United States Public Health Laboratory for examination, stress being laid on the various strains of the typhus group. The report on August 22 was as follows: agglutination for *Bacillus proteus* X 19 negative, *Pasteurella tularensis* negative, *Brucella abortus* negative and *Salmonella paratyphi* B positive in a dilution of 1:20. Complement fixation for Rocky Mountain spotted fever negative, endemic typhus negative, Q fever positive in a dilution of 1:4. Roentgenologic examination of the lungs was negative on August 25.

COMMENT

A tentative diagnosis of Q fever was made on the eleventh day based on the following findings: (1) Clinically the condition belonged in the typhus group. (2) there was an absence of rash. (3) there was a negative Weil-Felix reaction and also a negative reaction for other specific fevers. On the twenty-fifth day of the illness the complement fixation test was positive for Q fever.

The illness was most severe during the first two weeks at no time was the patient critically ill. Toward the latter part of the illness the devitalizing effect became apparent and a blood transfusion was given. Quinine was administered during the first three days with no effect. This was followed by moderately large doses of sulfadiazine for five days with no effect. The treatment then became one for fevers of long duration.

CONCLUSION

1 One should think of Q fever when clinically the disease resembles the typhus fever group, there is no rash and the Weil-Felix reaction is negative

2 A constant alert should be maintained throughout the war for fevers and diseases of the Orient.

FAMILIAL POLYPOSIS OF THE COLON

LIEUTENANT (JG) MORRIS T. FRIEDEL (MC) U. S. N. R.
and
E. G. WAKEFIELD, M.D.
ROCHESTER, MINN.

Harrison Cripps¹ is credited with recording the first observation that two members of the same family might have polyps of the rectum. Since this report many isolated family histories have been recorded. Some of these reports have consisted of two or three members of one generation or two or three generations who have had polyps of the colon. Such reports are of limited value. The larger families, such as the one reported herein and the one reported by Jungling² also are of limited value so far as human genetics is concerned. These reports are of limited value because family histories are notoriously inaccurate and also because not enough information concerning the general health of the family can be obtained.

The great number of members of a family like the one recorded herein and the one studied by Jungling definitely

CASE 1—A man aged 61 registered at the clinic in September 1921. He had had melena for two years and for six months had had alternating diarrhea and constipation. Proctoscopic examination established the diagnosis of rectal carcinoma. There were numerous polyps above and below the lesion, these polyps extended beyond the range of the proctoscope.

CASE 2—A woman aged 56 registered at the clinic in March 1932. For three months she had had pains in the lower part of the abdomen which were relieved by the passage of stool and flatus. Roentgenologic and proctoscopic studies revealed a carcinoma of the rectum and multiple polyposis of the colon. The adenocarcinoma was of grade 4 malignancy (Broders). The patient died of hepatic metastasis subsequent to removal of the rectal lesion.

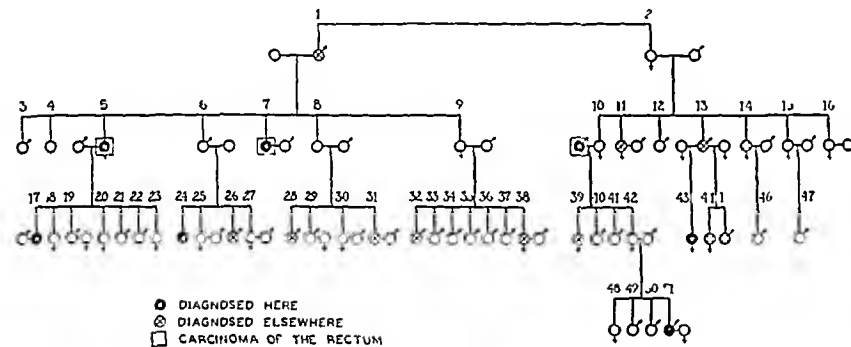

CASE 3—A woman aged 27 registered at the clinic in April 1932. She had had frequent bloody stools for four years. Roentgenologic and proctoscopic studies revealed multiple polyposis of the colon.

CASE 4—A woman aged 18 registered at the clinic in November 1934. For six months she had had four to six stools daily and had noticed gross melena for two months prior to her coming to the clinic. A diagnosis of multiple polyposis of the colon was made on the basis of proctoscopic and roentgen studies.

CASE 5—A woman aged 61 registered at the clinic in August 1935. She had had rectal bleeding for twelve months. Proctoscopic studies revealed a carcinoma of the rectum and multiple polyps above and below the lesion.

CASE 6—A woman aged 27 registered at the clinic in April 1932. She had had rectal bleeding for four years. Roentgenologic and proctoscopic studies revealed multiple polyposis of the colon.

CASE 7—A woman aged 27 registered on May 31, 1935, complaining of weakness. Results of examination were negative except for evidence of secondary anemia. She returned in October 1937, at which time she complained of alternating diarrhea (three or four stools daily) and constipation. Proctoscopic examination revealed numerous tiny polyps in the rectosigmoid. This condition has per-

Family tree showing incidence of polyposis of the colon

indicates that in some families there is a hereditary factor so far as polyps of the colon are epithelial proliferations which are potential carcinomas. Such polyps probably all will be carcinomas if the patient who has them lives long enough. Therefore, carcinoma of the rectum and colon among those who have polyps is certain to occur in time. But one must not be confused carcinoma arising in polyps of the colon is secondary to the polyps and is not a part of the hereditary factor.

As to the hereditary factor of disseminated polyposis of the colon when it is present, one can say that the disease is transmitted by both males and females. This is shown in the family tree. Both males and females suffer from the disease. The inheritance has been traced through several generations. At this point it must be emphasized that about half of the patients with disseminated polyposis of the colon who have been seen at the Mayo Clinic do not have this hereditary factor. Their family histories are not even suggestive that any other members of their families have or have had polyps of the rectum and colon.

REPORT OF CASES

sisted to the date of our report and has been verified by roentgenologic studies. In September 1937 appendectomy and the transcolonic removal of a polyp were performed. A diagnosis of grade 1 adenocarcinoma in an adenoma was made. In October 1940 ileosigmoidostomy was performed, and a polyp was removed from the transverse portion of the colon. This polyp also was found to contain portions of a low grade (grade 1) adenocarcinoma.

In the illustration is revealed such information concerning additional members of this family as was available to us. The family had originated in Germany and both the brother and sister (cases 1 and 2) were born there. At the time of writing it was impossible to gain any further information from Germany concerning the family. There are approximately forty-nine descendants of the brother and sister. Of these, nineteen or 39 per cent, had either multiple polyposis or a carcinoma of the large intestine. The disease was manifest in nine males and eleven females. Of the seven members examined at the clinic, two were males and five were females. Carcinoma of the rectum was present in three of these seven. Multiple polyposis of the colon was found in all the patients examined at the clinic.

SUMMARY

In about half the cases of multiple polyposis of the colon there is a definite hereditary tendency. This hereditary tendency does not produce any known genetic pattern. It is not sex-linked and is neither a mendelian dominant nor a recessive. In half of the cases the family history is entirely negative for polyps or carcinoma of the colon.

Special Article

HANDBOOK OF NUTRITION XXII

ADEQUACY OF AMERICAN DIETS

HAZEL K STIEBELING, PH D
WASHINGTON, D C

These special articles on foods and nutrition have been prepared under the auspices of the Council on Foods and Nutrition. The opinions expressed are those of the authors and do not necessarily reflect the opinion of the Council. These articles will be published later as a Handbook of Nutrition.—Ed

A description of the diets of a whole population can never be simple. Food habits vary from place to place and from season to season. They differ from family to family too, reflecting economic circumstances and cultural backgrounds. Even within a single family group diets of individuals vary more than is generally realized. The latter point, preserved in legend by the Mother Goose rhyme about Jack Spratt and his wife, has recently been spelled out in terms of its nutritional significance by Canadian investigators. Their studies show that among low income groups food tends to be distributed inequitably among family members.¹ As a rule, the men—the breadwinners—appear to fare best relative to nutritional needs, women and older children, worst. When there is scarcely enough to go around, mothers tend to sacrifice for other family members. Even so, however, teen age children with their high nutritional requirements often get less than enough.

Information regarding dietary levels in this country is available from two types of statistics. On the one hand are the United States Department of Agriculture's figures showing average quantities of various foods or groups of food disappearing in consumptive channels and long time trends in our nation's over-all consumption. These estimates are constructed from available data on production, imports, exports and changes in quantities in reserve (stocks) as of the beginning and the end of each year. On the other hand there are data from numerous family dietary studies which throw much light on the extent to which various groups of the population share in these national food supplies.

TRENDS IN FOOD CONSUMPTION IN THE UNITED STATES

Per capita food supplies in this country are bountiful compared with those of most other parts of the world. The per capita volume has remained fairly constant during the last three decades, but within the total the relative importance of various foods has shifted.² As charts 1 to 7 show, there has been a phenomenal rise in the consumption of sugar and citrus fruits, and an upward trend in the consumption of dairy products and fruits and vegetables on the whole. Paralleling these increases, there has been a decline in the consumption of potatoes, meats and grain products. From the standpoint of nutrition, certain of these trends in food

consumption have enriched the diets of American people while others have impoverished them. On the credit side, for example, is the increase in consumption of dairy products, fruits and succulent vegetables, on the debit side, the increase in consumption of refined sugar.

These shifts in consumption have not occurred to the same extent among all population groups. According to dietary studies made during the period 1885 to 1937,³ the decline in the consumption of grain products by village and city families has been greater among those with comparatively low food expenditures (\$1.25 to \$1.87 a week per person, 1935 retail food price levels) than among those with average and higher than average food expenditures. Among families spending less than average amounts for food, meat consumption fell to a low level in 1915-1924 and since that period has increased relatively little. In contrast, among families

Chart 1—Per capita consumption of cane and beet sugar (raw basis) in the United States 1909-1939

spending more than average amounts for food meat consumption declined relatively more in the decade 1915-1924 but since that period has increased considerably. The rate of increase in the consumption of milk and leafy green vegetables during the last fifty years has been of about the same order of magnitude among all expenditure groups, whereas the relative increase in the consumption of vitamin C rich fruits has been more striking at lower than at higher food spending levels.

On a per capita basis, the nutritive value of the aggregate assortment of uncooked food materials estimated as delivered to the nation's kitchens during the two periods 1920-1924 and 1936-1940 is compared in certain respects with the dietary recommendations announced at the 1941 National Nutrition Conference for Defense by the National Research Council's Food and Nutrition

From the Bureau of Home Economics, U. S. Department of Agriculture.

Board⁴ (table 1) It would appear that diets in this country could meet the recommendations for nutrients listed except in the case of calcium, riboflavin and thiamine (on a per hundred calory basis), provided the food was distributed equitably among the population

Chart 2—Per capita consumption of fresh apples and citrus fruit in the United States 1909-1941

The figures presented on nutritive content of our food supply tend to be high, however. They refer to food brought into the kitchen and take insufficient account of the losses of nutrients in the preparation of food and of the edible food waste. Only average quantities of inedible refuse were deducted. In contrast, the dietary recommendations of the National Research Council's board with which the nutritive values of food supplies are compared represent actual intake and do not make allowances for losses in cooking. Hence, the over-all picture drawn of dietary adequacy tends to be optimistic. Nevertheless, the differences between the two five year periods probably are reliable—little change in the nutritive value of diets with respect to food energy, protein, iron and most of the B vitamins but an upward trend in calcium, vitamin A value and ascorbic acid.

SOME FACTORS AFFECTING FOOD CONSUMPTION LEVELS

Averages for the country as a whole are useful chiefly as a background against which to discuss variations in consumption. The generous food supplies enjoyed by some families bring up national averages but confer no benefit on those having but meager resources. Dietary studies show that within a population families in the upper income classes tend to have a greater variety and abundance of food than their less prosperous neighbors. However, at each income level the larger the family the less ample the diet of each person tends

to be. Furthermore, there are wide variations in nutritive quality of diets even among those having equal economic resources, owing to differences in managerial ability and knowledge and skill in food selection and preparation.

This section of the paper will be confined to variations in diet reflecting differences in income, family size and management practices with some comparison of farm and nonfarm situations. These appear to be among the most significant, though by no means the only factors affecting family dietary levels. Most of the illustrations are taken from reports of large scale dietary studies made by federal agencies in 1936.

DIET IN RELATION TO INCOME

Comparatively little difference from one income class to another was found in 1936 in per capita consumption of grain products, of fats and in villages and cities, of sugar. On farms there appeared to be some increase in sugar consumption as incomes rose. Both in villages and cities and on farms there were moderate increases in the consumption of milk, eggs and meat at successively higher income levels with the rate of increase about the same for all of these groups of products. Of fruits and vegetables (other than potatoes and dried beans and peas) there was a decided increase in the quantities consumed as incomes went up. In general, however, the rate of increase in consumption accompanying successively higher incomes was greater in the lower ranges of the income scale—e.g., under \$1,500 a year—than in the upper. Table 2 illustrates these points.

Chart 3—Per capita consumption of fruits in the United States 1909-1939

As would be expected from such trends in consumption, diets of higher income groups tend to provide more protein, minerals and vitamins than those of low income groups, both absolutely and relatively to caloric value. The nutrients with respect to which diets of

low and high income groups differ most widely are calcium, vitamin A, ascorbic acid and riboflavin

Farm family diets differ from those of village and city dwellers in a number of respects. At comparable income levels farm groups consume per capita decidedly more of the important energy yielding foods—grain

Chart 4—Per capita consumption of vegetables in the United States 1909-1939

products, potatoes, mature beans and peas, sugars and fats, reflecting perhaps the heavier manual work, longer hours of toil and probably greater exposure to weather. Farm families consume more milk too. This is due, in part, to the fact that cows are milked on about three fourths of the farms in this country. Milk, then, is available for use by many families without direct cash outlay, and hence there are fewer economic barriers to its use. Furthermore, on farms there are more children per family than in urban areas. The census of 1940 showed that of every hundred persons on rural farms there were 32 persons under 15 years as contrasted with 22 in cities.

Farm families do not consume more than city groups of all kinds of food, however. In general, on a per capita basis, they tend to eat less meat, poultry and fish and less fruit and vegetables (other than potatoes and mature beans and peas).

Knowledge is still too incomplete to make possible a thoroughgoing appraisal of the nutritive adequacy of the diets of this nation. There is need for more information regarding both nutritive values of food as commonly eaten and human nutritional needs. But a provisional picture of the nutritive quality of diets of various population groups can come from the Bureau of Home Economics classification of family dietary records by their nutritive content.⁶

⁶ Stiebeling, Hazel K., Monroe Day, Coons, Callie M., Phipard, Esther F., and Clark, Faith, Family Food Consumption and Dietary Levels Five Regions Farm Series, miscellaneous publication 403, United States Department of Agriculture, 1941. Stiebeling, Hazel K., Monroe Day, Phipard, Esther F., Adelson, Sadie F., and Clark, Faith, Family Food Consumption and Dietary Levels Five Regions Urban and Village Series, miscellaneous publication 452, United States Department of Agriculture, 1942.

On the basis of these studies tentative estimates for 1936 indicate that about one fourth of the families in this country had diets that could be rated good, more than a third diets that could be considered fair and another third diets that should be classed as poor. Recently the food records from these studies have been reclassified by separating from those formerly called good the ones that provided the several nutrients in the quantities recommended in 1941 by the National Research Council's Food and Nutrition Board. In this paper these diets of higher nutritive value have been labeled excellent. Considerably fewer than a fourth of the nation's families in 1936 would have been in the excellent diet category.

At successively higher incomes there generally is found an increasing proportion of families with diets that could be graded excellent. This follows from the larger quantities of milk, butter, meat, eggs, succulent vegetables and fresh fruits usually found in the more expensive diets. Chart 8 shows the proportion of families at different income levels with diets classed as excellent, fair or good. (The chart is based on food records obtained in 1936 from village and city families of parents and one or two children living in the North and West.) In the income class \$500-\$999, about 10 per cent had excellent diets, in the class \$3,000 and over, 40 per cent.

Both on farms and in villages and cities, family diets vary in their richness with respect to different nutrients at any given level of food expenditure. Take, for example, diets of families in the North and West

Chart 5—Per capita consumption of dairy products in the United States 1909-1940

with food worth 30 to 40 cents a day per man—a not uncommon level of food expenditure in 1936. About 70 per cent of the village and city families in this population group had food that provided less calcium than that recommended by the Food and Nutrition

⁷ Stiebeling, Hazel K., Are We Well Fed? Miscellaneous publication 430, United States Department of Agriculture, 1941.

Board Thirty per cent had less vitamin A, 70 per cent less ascorbic acid and 75 per cent less riboflavin. On farms, 30 per cent of families with food valued at 30 to 40 cents a day per man had diets providing less than the recommended quantities of calcium, 20 per cent less of vitamin A, 60 per cent less of ascorbic acid and 40 per cent less of riboflavin. (Because farm furnished food was valued at less than urban retail prices, a given sum represents a greater total volume of food among farm than among nonfarm groups, this fact as well as characteristic differences in diets, discussed earlier, accounts for the differences in nutritive value just noted.)

No one should assume that all families with diets falling short of desirable goals suffer from obvious nutritional deficiencies. But the diets of many such families are amenable to improvement, the degree dependent on the extent to which the diet falls short of optimum. Many diets that are "passable" in the sense that their nutritive quality is not questioned by the general public cannot be considered satisfactory by the scientist with an insight into the contributions that food at its best can make to the well-being of the individual and the race.

Food plays an important part in determining the composition of body tissues and the fluids that bathe the cells, forming what Sherman calls the "internal environment" in which life itself goes on.⁸ Differences in this environment, many of which may be too small to be measured by present methods, definitely affect the plane on which physical and mental functioning

sure the incidence of malnutrition in the United States merely by the number of death certificates that list malnutrition as a primary cause, the country would appear to be singularly free from this reproach. In recent years considerable progress has been made in developing technics for measuring nutritive status and

Chart 6—Per capita consumption of meats in the United States, 1909-1939.

go on. As far as the immediate or long term well-being of a person can be improved through dietary betterment, that person falls short of being truly well fed.

A nationwide study has not been made of the prevalence of inferior nutritional status. Were one to mer-

revealing incipient malnutrition through biochemical or physiologic tests. Viewed broadly, the results of such studies support conclusions derived from an appraisal of diets of various population groups. To cite from but one—a study made recently in New York City comparing the nutritive status of children in a school serving chiefly families of the lower income group with those in a private school patronized by the more well to do.⁹ In the low income group more than three fourths of the city children examined showed some stage of avitaminosis A, three fourths

some degree of ariboflavinosis and one half plasma levels of ascorbic acid below 0.6 mg per hundred cubic centimeters. In the high income group less than 3 per cent of the children showed mild ariboflavinosis and less than 6 per cent had ascorbic acid levels below 0.6 mg per hundred cubic centimeters. Studies in other communities also show differences in nutritive status associated with dietary differences characteristic of various economic groups.

DIET IN RELATION TO SIZE OF FAMILY AND INCOME

The size of the family as well as its income determines how much money may be spent for the food of each person. For example, in small North Central cities in 1935-1936, families of two persons with incomes of \$500 to \$750 spent an average of about 11 cents a meal per person. When there were four in the family, it seemed to take incomes of \$1,250 to \$1,500 to afford approximately 11 cent meals, and with five or six in the family, incomes of \$2,000 to \$2,250.¹⁰ While the larger sized family can effect some economies in the purchase of food as well as in its preparation, these economies seldom compensate for the progressive reductions in average food expenditures per person made within an income class by groups of families progressively larger in average size. In general, within an income class, the larger the family the less money is available for the food of each person and therefore the smaller the quantities of protective food bought for each person and the smaller the proportion of families with diets that can be classed as excellent.

DIET IN RELATION TO MANAGEMENT PRACTICES

At every level of money value of food, some families succeed in obtaining better diets than others. Granted that there are minimum expenditures below which fully adequate diets cannot be purchased and that increases in economic resources simplify the matter of obtaining satisfactory meals, it should be noted that even liberal

likely to keep her family well fed. She knows how to buy food economically, to prepare it appetizingly and to serve it attractively. Without such skills and thrift in market and kitchen, a family may be aware of the importance of good nutrition but be unable to achieve it within the limits of its resources.

TABLE 1—Comparison of Nutritive Value of Food Estimated to Be Delivered to Nation's Kitchens in Two Five Year Periods with 1941 Dietary Recommendations of National Research Council's Food and Nutrition Board

Nutrient	Nutritive Value per Capita per Day of Total Food Delivered to Kitchens * in		Per Capita Allowances † Based on 1941 Recommendations of National Research Council's Food and Nutrition Board
	1920-1924	1940-1946	
Food energy calories	3,280	3,220	2,800
Protein Gm	84	82	66
Calcium Gm	0.77	0.82	0.9

Riboflavin mg	1.7	1.8	2.3
Thiamine total mg	1.7	1.7	1.6
Thiamine per 100 calories mg	0.05	0.05	0.057
Ascorbic acid mg	80	90	70

* Computations based on unpublished data on consumption supplied by O. V. Wells, Bureau of Agricultural Economics.

† Allowances suggested by the committee for seventeen age-sex activity groups were weighted by the number of persons in each group as judged from the 1940 census of population.

Families in the higher income classes are somewhat more likely to buy satisfactory diets than those with more limited economic resources, even with the same expenditures for food. Not only do family members in the higher income classes usually have the advantage of a longer period of formal education, but they are the more likely to have radios and periodicals that bring up to date nutrition information, including facts regarding food requirements, food values and selection and wise food preparation. In addition they are more likely to have the resources and storage space that are needed for buying food on a relatively large scale. The hand to mouth or meal by meal buying that many low income families resort to is, of course, a relatively expensive practice.

Farm families face additional problems in safeguarding the nutritive quality of diets. Most of them must raise a substantial share of their food supply if they are to be well fed. This requires labor. It requires land for food and feed and capital for investment in cows, pigs, chickens and farm equipment for production. It requires managerial ability in planning ahead for months and even years. It requires knowledge and skill for production and conservation of food. It requires courage when weather hazards or uncontrollable insect pests bring ruin to months of work. But well planned home food production programs enable farm families in many communities to enjoy diets of enhanced nutritive value.

A dollar's worth of milk, eggs, meats, vegetables and fruits from the farm (valued at prices farmers would pay if they bought them from neighbors) represents much higher returns in the nutritive essentials than a dollar's worth of staple products such as white

Chart 8—Percentage of families in various income classes having diets of specified nutritive value. Dotted area indicates excellent; diagonal lines fair; black poor.

expenditures for food do not guarantee adequate diets. The homemaker who is a good manager and a good cook, who keeps up to date on food values and nutrition and applies this knowledge to her meal planning is

10 Bradv Dorothy S. Monroe Day Phelps Elizabeth and Rainboth Fifth D. Family Income and Expenditures Five Regions Part 2 Family Expenditures Urban and Village Series miscellaneous publication 1946 United States Department of Agriculture 1940

flour, lard, sugar and coffee bought at the retail food store. Dietary studies among farm groups have shown that within a given income class, especially at the lower range of the income scale, adequacy of diet depends much less on the cash spent for food than on the quantity and variety of farm-furnished food. Of course, highest returns for productive effort will come if planning—with human needs in mind—precedes the work of production. Agencies working to help farm families improve their living levels have placed increasing emphasis on planning ahead for the production and purchase of an adequate family food supply on a year-round basis.

THE DIETARY SITUATION IN THE EARLY 1940'S
AS COMPARED WITH THE MIDDLE 1930'S

There are reasons to believe that diets in the United States were better in 1940 and 1941 than five years earlier. Many families had higher incomes and could

highlighted the subject so that it has become the focal point for the research, teaching and action programs of an increasing number of persons, groups and agencies. Following this conference there has been renewed interest in establishing state and local nutrition committees whose function it is to integrate the work of all groups that impinge on the problem of better diets. This action has greatly stimulated the demand for simple educational material and effective methods to help families redirect their dietary habits and to revamp their management practices for the sake of improving dietary levels.

Public interest in nutrition also has led to growing concern regarding the nutritive value of common foods and the effect of processing on them. On the recommendation of the National Research Council's Food and Nutrition Board, millers and bakers began in 1941 to put on the market an "enriched" white flour

TABLE 2—Per Capita Food Consumption Farm and Village and City Families in the United States. Estimate of Average Quantities Consumed of Eleven Food Groups per Year by Income Class 1935-1936*

buy more and better food. With the acceleration of the defense program, many unemployed got jobs, WPA employed workers got better jobs, part-time workers got full-time employment, and some workers in defense industries got higher wages. Food prices were at a low level in 1940 and early 1941, so that despite the rises in the cost of food during the latter part of 1941 incomes of wage earners bought more food in both 1940 and 1941 than five years earlier. Indeed, it seems possible that, with their increased power to buy, at least one family out of every seven that had had poor diets in 1936 was able to obtain a fair or good diet in 1941.

Public interest in food has been on the increase for many years, thanks to the cumulative effect of sound educational programs. The National Nutrition Conference for Defense called by the President in 1941

and bread, thereby contributing to the thiamine, nicotinic acid and iron content of diets of families customarily consuming large quantities of these products. Canadian and British scientists and policy makers have recommended that flour in those countries be milled somewhat less highly, so that more of the vitamin and mineral content of the original berry is retained, thus securing without "restoration" a product much more nutritious than patent flour.

The manufacture of vitamin concentrates and the production of synthetic vitamins have been stepped up greatly during the last few years. These special foods can play a useful role in dietary reinforcement, although their indiscriminate use often wastes money which might better be spent for ordinary food.

Contributing directly to the dietary improvement in recent years are the several food distribution pro-

grams of the United States Department of Agriculture. The food stamp program, direct distribution, school lunches and arrangements for low priced milk help channel an enlarged share of national food supplies to needy persons.¹¹ As a result, almost 175 million dollars' worth of additional food was made available to the underprivileged in 1940-1941. Although this amount is small compared to the total food bill of the country, the programs are of very great importance to the participants.

In 1940-1941 a monthly average of 8.8 million persons in family groups received foods made available under the direct distribution program, and an average of 2.9 million persons a month participated in the food stamp program. The school lunch program reached an average of 2.9 million children a month during the year (4.7 million in March, the peak month). Under the penny milk program, more than 900,000 children in eight cities, principally New York, purchased nearly 12 million quarts of milk. About 460,000 persons in family groups in six cities participated in low priced milk programs, purchasing 68 million quarts.¹²

As far as studies have been made,¹³ it seems clear that participants in these programs have better balanced as well as more abundant diets than nonparticipants of equal economic status. Something of the variety of the foods made available through the programs is indicated by the following list: butter, eggs, pork, lard, potatoes, other fresh vegetables, dry beans, rice, corn meal, wheat flour (white and whole wheat), oranges, grapefruit, apples and prunes. All these foods were bought in comparatively large quantities with blue stamps in 1940. (The list of foods available under the several programs varies from month to month.) These foods are not merely superimposed on supplies that

would normally be purchased. Participating families follow the procedure of farm families—modifying their usual purchases somewhat, the better to complement those obtained without direct outlay.

Both the school lunch and food stamp program in 1940 reinforced the diets of participants in many directions, but especially with respect to vitamin A, thiamine and ascorbic acid. Food obtained directly through the program contributed little, however, to correcting the frequently recurring shortages of calcium and riboflavin. The fact that the programs were in operation, however, contributed to this end. For example, studies have shown that stamp plan participants buy more milk than comparable nonparticipants (milk is an economical source both of calcium and riboflavin, among other nutrients). Furthermore, sponsors of school lunches in many communities provided milk to supplement meals that could be prepared from foods furnished by the Surplus Marketing Administration.

The two government aided milk programs directly encouraging milk consumption among needy families were on a small scale in 1940. That families will greatly increase their purchases of milk when it is available at a low price is illustrated by figures from a study made in Washington, D. C. Before the program was begun white participants consumed milk in all forms (fluid or evaporated or in the form of cheese or ice cream) in quantities equivalent in nonfat milk solids to 2.50 quarts of fluid milk a week per person and to 4.06 quarts after the program went into effect, among Negro families, the average quantity was equivalent to 1.89 quarts a week per person during the preprogram study, compared with 3.48 quarts afterward.

It is difficult to estimate the net effect on dietary levels of any public aid food distribution programs. How much the nutritive value of the customary diets of families on relief is improved depends on many things, including the usual food consumption of families before their participation in the program, the variety and quantity of foods purchasable or distributed through the programs and the adjustments in usual diet patterns that families make because of the foods available under the program.

Over-all per capita consumption of many foods was higher in 1940 and 1941 than in 1936 as a result of the combined influence of educational programs, increased power of consumers to buy, food distribution programs and more abundant food supplies. Gains were greatest in fruit and fresh vegetables. Consumption of fresh citrus fruit was more than a third higher—other fruit and fresh vegetables between 10 and 15 per cent higher. Consumption of meat and eggs was 8 to 10 per cent higher, but of dairy products less than 5 per cent higher. There was a slight decrease in the quantities of grain products and potatoes. These shifts probably have meant considerable increases in the ascorbic acid content of American diets and some increase in the consumption of protein, thiamine and riboflavin.

To provide the nutrients in quantities and proportions recommended by the National Research Council's Food and Nutrition Board, the Bureau of Home Economics has evolved a number of plans for market lists at various cost levels.¹⁴ These market lists are in terms

11 The food stamp program was operating early in 1942 in areas containing more than half of the nation's population. Blue stamps given under certain arrangements to public aid families serve to increase by about 50 per cent the food buying power of those taking part in the program. Commodities designated by the Secretary of Agriculture are available at local stores in exchange for the blue stamps. Blue stamp foods listed during January 1942 for example included eggs, butter, pork, fresh pears, apples, oranges, grapefruit, fresh vegetables including potatoes, dried prunes, dry beans, corn meal, hominy (corn), grits and various forms of wheat flour.

Where the food stamp program is not in operation commodities bought by the Surplus Marketing Administration under programs designed to strengthen farm markets are distributed by welfare agencies to public aid families. The supplies so distributed are in addition to what these needy families are able to buy or otherwise obtain.

Increasing quantities of food are being distributed for use in school lunch programs for needy children. The lunches may be made in whole or in part from the commodities supplied by the Surplus Marketing Administration. In most places foods needed to round out the meals are supplied by the local community groups sponsoring the program in the schools.

Greater consumption of fluid milk is being encouraged among underprivileged families by low priced milk programs. These are of two types—one supplies milk to public aid families at a low price and the other makes milk available for use by school children at a penny a half pint. The low price at which the milk is supplied to eligible persons is made possible through provision for a special price to be paid producers and through a federal indemnity payment to handlers whose bids for furnishing the milk are accepted. The indemnity payment plus the price received from sales, reimburse each handler for the milk and the handling and distributing services. The special producer price paid for milk used in the programs is lower than that for regularly sold fluid milk but higher than the price producers receive for so-called surplus milk used for manufacturing purposes.

general enough to be followed in any part of the country. If every one in the United States should follow such plans and thus redirect dietary habits, 1936 levels of consumption for the country as a whole would be increased by at least 50 per cent in milk and by at least 50 to 100 per cent in vitamin C rich fruits and the nutritionally important leafy, green and yellow vegetables. The increases in the consumption of milk in its various forms—skim milk, fluid and dry, cheeses and evaporated milk as well as whole fluid milk—would help enrich diets in both calcium and riboflavin. At the present time too large a proportion of our skim milk—a product that supplies all the nutrients of milk below the cream line—is used in animal feed rather than for human consumption.

Whether in the war year 1942 the dietary gains of the recent past can be maintained or accelerated and improvements in still other directions initiated time alone will tell. Enormous quantities of food are needed for our own civilian population and armed forces and for those of other countries resisting aggression. Unless enough food and food of the right kind is produced, dietary levels will fall. To meet these enlarged needs the farmers of this country are undertaking in 1942 the greatest program of agricultural production in our history. Goals that tax farm capacity have been established for all products. In setting these goals, consideration has been given to the dietary needs of the people of the United States as well as to anticipated domestic and foreign market demands. While the increases necessary to provide nutritionally adequate diets for our entire population cannot be made in a single year—this would call for changes in dietary habits as well as in purchasing power and food production—steps in these directions are being taken.

If agriculture achieves its 1942 goals and no demands develop beyond those foreseen in early 1942, per capita consumption of domestically produced food can be maintained at a level as high as or higher than in the recent past. If these conditions prevail there should be further strengthening rather than any weakening in our nutritive status. Expected reduction in imports will result in only relatively minor changes in our dietary habits for 1942-1943. The smaller supplies of imported sugars may bring about the partial replacement of a highly refined product by foods having higher mineral or vitamin value. Unless oil production can be increased greatly (as is the plan) there may be some shortage of oil by 1943, but reduced supplies only of sugar and oil augur no ill for the nutritive level of this country. In fact, they may even bring improvement.

It is well to keep in mind, however, that there may be unexpected demands on our food supplies. In January 1942 the Secretary of Agriculture has said—"We are one of the twenty-six United Nations whose resources for winning the war are to be shared and placed wherever there is need. We don't know how many people we shall be called upon to feed outside the borders of the United States. Neither do we know how great the difficulties in the way of increasing our farm production may become, through shortages of rubber, steel, fertilizer and so on, but farmers and the processors and handlers of farm products are going to do their level best to meet the goals for higher production in 1942."

Whatever lies ahead, all of us as consumers can make a real contribution to dietary adequacy in this country if we will renew our efforts to use food wisely by avoiding waste and by bringing food habits closely into line with the teachings of the modern science of nutrition. Only thus can we translate into reality the oft repeated challenge "Let us make America strong by making Americans stronger."

Council on Pharmacy and Chemistry

THE COUNCIL HAS AUTHORIZED PUBLICATION OF THE FOLLOWING STATEMENTS
AUSTIN E. SMITH, M.D., Secretary

ANNUAL MEETING OF THE COUNCIL ON PHARMACY AND CHEMISTRY

The Council on Pharmacy and Chemistry of the American Medical Association convened at the Association Headquarters, Oct. 2-3, 1942. Those in attendance were Drs. David P. Barr, S. W. Clausen, H. N. Cole, Morris Fishbein, E. M. K. Geiling, Chester S. Keefe, James P. Lenke, Stuart Mudd, F. M. Nelson, W. W. Palmer, William C. Rose, Elmer L. Sevringhaus and Austin L. Smith. In addition to the members of the headquarters staff there were present, either for certain discussions or during the entire meeting: Dr. Ernest E. Irons, Secretary of the Board of Trustees; Dr. Robert P. Herwick, Chief, Drug Division of the U. S. Food and Drug Administration; Dr. Milton Valdez of the National Institute of Health; and Dr. Donald Wilbur, Secretary of the Council on Dental Therapeutics. In the absence of the Chairman, Dr. Torald Sollmann, the meeting was opened by Dr. W. W. Palmer, Vice Chairman.

The following is an abstracted report of some of the more important discussions and actions.

Dermatophytosis—Athlete's Foot, Preparations.—The Council has thus far not accepted any preparations specifically for use in this condition. After extended discussions the Council took two actions: (1) authorization of the appointment of a subcommittee of the Council to draw up a plan of procedure for the consideration of preparations proposed for use by the public for the prevention of fungous skin infection (dermatophytosis) and preparations for the treatment of this infection to be used by the medical profession; (2) authorization of a status report concerning the prophylaxis and treatment of fungous skin infection by men with special knowledge in this field under the supervision of a Council member.

Vitamin Preparations.—The Council gave further consideration to this question and voted that no objection be made against advertising to the public of such preparations when the dosage is for prophylactic use only and provided such advertising is not objectionable under the Council's rules concerning direct advertising. The Council voted further that when such preparations are offered for therapeutic use, generally when the dosage prescribed is more than three times the minimum daily requirement [FDCA, Sec. 403 (j)], the advertising should be directed only to the medical profession. The Council also will publish a statement on the declaration of dosage on the label.

Contraceptives.—The Council considered recommendations of its Committee on Contraceptives for a method of procedure for consideration of contraceptive preparations and devices. The Committee's report was adopted, providing also for a further report on scope and criteria from the Council's Advisory Committee on Contraceptives. This advisory committee consists of men with special knowledge and training in this field.

Artificial Mineral Waters.—After extensive discussion the Council declared artificial mineral waters nonessential modifications of natural waters and voted that natural mineral waters be considered only as one feature prescribed by spas and health resorts and that they be not considered for acceptance by

the Council as individual products as there is no convincing evidence to show that the many therapeutic claims, which are made attendant to these preparations when bottled for individual use, are valid

Metric System—The Council considered the question of abandoning in its publications the use of the apothecary system and the use only of the metric system. After extended discussion the Council voted that, in future editions of New and Nonofficial Remedies, Useful Drugs, the Epitome of the U S Pharmacopeia and National Formulary and in Interns' Manual (with the consent of the Council on Medical Education) as well as in other Council publications, the metric system only will be used and that conversion tables for the apothecary system will be included in all publications. The Council further authorized the appointment of a committee to draw up a statement for publication at the time the foregoing action goes into effect, calling attention to trends such as the use of the metric system in vitamins and sulfonamide preparations and indicating the Council's desire for rapid progress in this matter.

Scope, Official Articles—The Council discussed the question of the continued inclusion in New and Nonofficial Remedies of brands of drugs which have become official by reason of adoption in the U S Pharmacopeia. Although the Council's rules state that articles official in the U S Pharmacopeia or National Formulary are exempted from consideration by the Council if they are marketed under the official name or a name which makes the official status evident, and if no unestablished therapeutic claims are made for them, a number of brands of official preparations are listed in New and Nonofficial Remedies. The Council voted that the status quo in regard to the pattern of admitting articles to New and Nonofficial Remedies be observed within reason for the duration of the war, and that all official preparations be reviewed with the express purpose of elimination from New and Nonofficial Remedies of all those the retention of which seems to serve no useful purpose. The Council also voted that products which have been official for no more than twenty years will be considered for inclusion or retention in New and Nonofficial Remedies, also all serum and vaccines, and arsenicals for the treatment of syphilis.

Articles Accepted But Not Described—For many years the Council has carried as an addendum to New and Nonofficial Remedies a "List of Articles and Brands Accepted by the Council but not Described in N N R". This was at first intended to be a list of articles exempt from the Council's consideration, such as official preparations, but has grown to include a miscellany of medicinal and nonmedicinal articles. The Council discussed the usefulness of such a list and voted that it now be deleted as a separate section from the book. Under the Council's rules this action cannot be completed until the expiration of the term of acceptance for the articles of this list now standing accepted. Articles whose usefulness justify retention will be inserted in an appropriate part of New and Nonofficial Remedies.

Censorship of Published Description of Articles—The Council has been informed of the decision of the local Office of Censorship and the Board of Economic Warfare that statements of description or methods of preparation of new drugs on their original publication in THE JOURNAL should be subject to censorship in the interest of national defense. The Council voted to adhere to this decision and as a consequence for the duration of the war will eliminate from descriptions published in THE JOURNAL such statements as are disapproved by the authorities concerned or at the discretion of the Council and editorial offices. These statements will be available, however, in New and Nonofficial Remedies.

Medical Pharmaceutical Cooperation—A report of the committee to the Council concerning the Medical-Pharmaceutical Cooperation was made. The Council agreed to participate in another meeting which is to be arranged with representatives of the pharmaceutical profession.

MENADIONE BISULFITE

The Council adopted the term Menadione as the nonproprietary designation for 2-methyl-1,4-naphthoquinone (THE JOURNAL, Jan 17, 1942, p 226). Subsequently two pharmaceutical manufacturers corresponded with the office of the Council regarding water soluble derivatives of menadione, one of the firms submitted a product which was believed to be a sulfonated derivative of menadione but which, on examination in the A M A Chemical Laboratory, proved to be a sodium bisulfite addition product of menadione.

In order to avoid confusion in the literature it is pointed out that published clinical studies which have dealt with the use of the compound 2-methyl-1,4-naphthohydroquinone 3 sodium sulfonate are in fact studies based on menadione-sodium bisulfite.

The Council has now adopted the term Menadione Bisulfite as a nonproprietary designation for the water soluble monosodium bisulfite addition product of menadione, and the interested manufacturers have been so informed.

NEW AND NONOFFICIAL REMEDIES

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED AS CONFORMING TO THE RULES OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO NEW AND NONOFFICIAL REMEDIES. A COPY OF THE RULES ON WHICH THE COUNCIL BASES ITS ACTION WILL BE SENT ON APPLICATION.

AUSTIN E SMITH M D Secretary

PURIFIED PROTEIN DERIVATIVE OF TUBERCULIN (See New and Nonofficial Remedies, 1942, p 531)

The following dosage form has been accepted

SHARP & DOHME, INC, PHILADELPHIA

Vacule Ampoule-Vial Lyovac Tuberculin Purified Protein Derivative Containing an amount of lyophilized tuberculin purified protein derivative sufficient to yield at least 1 test dose per 0.25 cc of restored solution, packaged with a 0.25 cc ampoule of phosphate buffer solution for dilution, preserved with 0.5 per cent of phenol. Available in first test strength and second test strength. Also marketed in 10, 100 and 250 Vacule Ampoule-Vials packaged with sufficient phosphate buffer solution preserved with 0.5 per cent phenol to yield 15 cc, 125 cc and 30 cc respectively, of restored solution in either the first test strength or the second test strength.

SULFATHIAZOLE (See New and Nonofficial Remedies, 1942, p 150)

The following dosage form has been accepted

DRUG PRODUCTS COMPANY, INC, LONG ISLAND CITY, N Y
Pulvoids Sulfathiazole 0.5 Gm (77 grains)

DIETHYLSTILBESTROL (See THE JOURNAL June 20, 1942, p 635 and the Supplement to N N R, 1942 p 26)

The following dosage forms have been accepted

ABBOTT LABORATORIES, NORTH CHICAGO, ILL

Ampoules Diethylstilbestrol in Oil, 0.5 mg per cc
1 cc in sesame oil

Ampoules Diethylstilbestrol in Oil, 10 mg per cc
1 cc in sesame oil

Tablets Diethylstilbestrol 0.1 mg 0.25 mg, 0.5 mg
1 mg and 5 mg

Vaginal Suppositories Diethylstilbestrol 0.1 mg and 0.5 mg

THEOPHYLLINE WITH ETHYLENEDIAMINE-U S P (See New and Nonofficial Remedies 1942 p 332)

The following dosage form has been accepted

Wm S Merrell Co, Cincinnati

Aminophylline Tablets 0.1 Gm (15 grains)

ASCORBIC ACID-U S P (See New and Nonofficial Remedies, 1942 p 564)

The following dosage forms have been accepted

JOHN WILEY & BROTHER, INC, PHILADELPHIA

Tablets Ascorbic Acid 50 mg and 100 mg

TRANSPORTATION OF DISEASE AGENTS

The movement of great numbers of men and women in the armed forces and in industry, the speed of transportation and the great variety of the regions concerned cause the United States Public Health Service to be faced with extraordinary problems in the prevention of importation of diseases into the continental United States. The ramifications of the problem are suggested by two recent reports from the Public Health Service. The first, by Parker,¹ deals with *Ornithodoros* ticks as a medium for the transportation of disease agents. Some of these ticks harbor in their tissues for a long time certain disease agents of which they are not known to be spontaneous hosts or transmitters. Ticks of this genus must therefore be considered as a possible medium for the transportation of disease agents such as rickettsiae and viruses when long periods of transit are involved.

Three attempts to use ticks of the genus *Ornithodoros* as a medium for importing from foreign countries disease agents of which they are not known to be normal hosts or vectors were successful. The diseases, the tick species and the minimum intervals between the ingesting of blood of infected guinea pigs by the ticks and the subsequent recovery of the disease agents from them were, for Tobia petechial fever, *Ornithodoros rudis*, eleven days and fifty-three days, for South African tick bite fever, *Ornithodoros moubata*, thirty-six days, for spring-summer encephalitis, *Ornithodoros moubata*, forty days. The recoveries of the causative agents were not made by tick bite but by injecting guinea pigs with saline suspensions of the tick tissues in the case of the rickettsial diseases and a broth suspension in the case of spring-summer encephalitis.

Olesen and Sherrard² discuss variations in rat infestation on vessels. Since 1940, they say, the number of fumigations of vessels has gradually increased and the

average rat recovery from each vessel has been greater than during previous years. This has been due to the considerable increase in the number of tramp vessels coming to New York. Over such vessels competent sanitary supervision has not been heretofore exercised. As Olesen and Sherrard point out, it is not pleasant to contemplate the effect on the public health or on the war effort of the introduction of quarantinable diseases into the United States. Therefore it becomes increasingly important to maintain rat control as well as other precautions on arriving vessels. The difficulty of performing the requisite steps in the face of the secrecy necessarily attending ship movements, the loss of trained personnel, the quick turn around of ships and other factors is readily apparent. From reports such as these however, it is clear that the United States Public Health Service is thoroughly aware of its responsibilities in this regard.

PROSPECTS AND PROGRESS IN INDUSTRIAL HEALTH

Modern preventive industrial medicine was born in the first world war, then declined in the postwar years, only to regain lost ground and to uncover many new fields of usefulness during the period of preparedness and conflict in the Global War. The urgent necessity for conserving the health of essential war workers is unquestioned. Leaders in government, industry and medicine agree that this objective is of utmost importance, second only, in fact to the health and medical requirements of the armed forces. The benefits of prevention of sickness and accident are equally valuable in peace, the only variables being urgency and the number of persons involved. Is this renaissance likely to subside again after the present unusual stimulus of production for war is over?

The force of interest in industrial medical organization will not subside as readily as it did twenty years ago. Large industry will continue to support a maintenance system which has demonstrated its ability to promote better production, lower absentee rates and improved labor relations. A major function of medicine and industry during the next few years will be the production of similar advantages for the small plant. The structure of governmental industrial hygiene services was largely undeveloped ten years ago, now it flourishes in every industrial state. The spread of dependable industrial health service is best consummated where correlation exists between the practicing medical profession, nursing and these public agencies for investigation and consultation in industrial hygiene. In this direction lies the hope for conservation of health in the small plants.

Much interest is developing in labor management committees now widely organized in war production

1 Parker R. R. *Ornithodoros* Ticks as a Medium for the Transportation of Disease Agents. *Pub. Health Rep.* 57: 1963 (Dec. 25) 1942.

2 Olesen Robert and Sherrard G. C. Variations in Rat Infestation on Vessels. *Pub. Health Rep.* 57: 1966 (Dec. 25) 1942.

plants and in the possible relation of such committees to industrial health administration. This type of organization is strongly advocated by the War Production Board. Advocates suggest that many of the former causes of apprehension and militant objection by labor toward certain phases of industrial medicine could be effectively overcome by such arrangements. The medical profession has always felt that the interests of employer and worker are close together where health is concerned.

The trend toward prevention in industry has tended in recent years to modify the need for purely remedial medicine and surgery. This current will be reversed by the casualties of war and the reintegration of the disabled into useful employment. Rehabilitation, both physical and vocational, must therefore become a predominant medical problem, so that maintenance of the handicapped in gainful occupation will occupy medical and surgical minds for years. Welcome also is the attention that rehabilitation and prevention are apparently receiving from administrators of workmen's compensation.

The changing nature of the work force emphasizes the need for medical and hygienic supervision in industry. Millions of women are demonstrating ability to compete on equal terms with men in some occupations, they introduce new problems in industrial medical supervision. In one corporation the frequency rate of absenteeism due to sickness runs 320 per thousand for women compared to 89.1 for men, and the average time loss is forty-two days.

Innumerable proposals appear concerning techniques for supplying preventive medicine and medical services to workers. One such plan offers health insurance with labor shouldering a proportionate share of the cost as a means to minimize many of the perplexing problems of administration of workmen's compensation. Such proposals must be examined with care and tested scientifically to determine their advantages and disadvantages. When sufficient data become available, medical economists may evaluate such plans more accurately.

STATE INDUSTRIAL HEALTH PROGRAMS

The movement toward more and better preventive industrial medicine has received force and direction from committees on industrial health in the state medical societies. Following the recommendations of the Council on Industrial Health, these agencies were to contain representation from private practice, industrial practice and the state bureau of industrial hygiene, all to assist in focusing the interest of every element in medicine on the physical welfare of workers. Already significant advances have been made. When the full implications unfold, no other committee in the structure of medical organization in each state is likely to exert

more influence on the nature and standards of medical practice.

One of the principal obstacles to widespread industrial medical activity is lack of public interest, particularly among the managers of small plants. The fault is not that of medicine alone, it is equally a responsibility of management and labor. State medical society committees on industrial health have established excellent working relations with state manufacturing associations and are bringing directly to them dependable information on the benefits of competent industrial medical supervision. Representatives of organized labor need to be approached to secure cooperation in the development of medical and hygienic programs in large and small plants and also in the province of general health education. Workers spend far more time off the job than on it. Ordinary illness plus the combined effects of poor housing, wrong nutrition and injudicious use of leisure time are the most prolific causes of absenteeism due to sickness.

Two other phases of activity by state committees contain the secret of successful advancement of industrial health. If any considerable degree of public acceptance is to be developed, physicians, hygienists and nurses must be capable of meeting these new demands. Much effort is now being exerted to supply the medical profession with an awareness of modern industrial health methods. Much remains to be done, however, largely under the immediate stimulus of state medical organizations.

Already some of the state committees have organized cooperating units in the medical societies of industrial counties. Efforts in the counties should be undertaken in accordance with accepted community medical practice and public health administration. The type of committee representation described for the states is equally important in counties. Recommendations have already been published about a county medical society program in industrial health.¹ These committees must exercise medical initiative and leadership in any community industrial health department. Opportunities are numerous for local investigation of causes of absenteeism, for correlation of interested community health facilities, for education of the public to the advantages of preventive industrial medical service and for continuous instruction of the profession and ancillary groups about advances in industrial medicine, surgery and hygiene. It is through responsive activity in this field by individual practitioners that satisfactory contributions to the war production effort will be made by the medical profession.

Current Comment

PHYSICIANS URGED TO RELEASE QUININE SUPPLIES

Every physician is urged to contribute to the National Quinine Pool¹ all supplies of quinine and other cinchona salts and alkaloids not absolutely essential in his practice for the treatment of malaria. These compounds are needed to maintain an adequate stockpile of antimalarial agents for use in the armed forces. Although synthetic substances such as atabrine are being produced in enormous quantities and are used wherever possible, there are many conditions for which the drug of choice is quinine. Until the war is over little cinchona bark of good quality will be forthcoming. The currently available barks from South America are of a low grade and sufficient only for the manufacture of totuquine, which is satisfactory for domestic use. The provisions of conservation orders M-131 and M-131A² essentially restrict the sale, transfer, delivery or use of quinine salts and alkaloids to the treatment of malaria. Quinidine is an exception which may be used in the treatment of certain heart conditions. Such restrictions will permit physicians to contribute unused and opened quinine supplies to the National Quinine Pool, care of the American Pharmaceutical Association, 2215 Constitution Avenue, Washington, D. C. Each package received will be tested for identity, pooled and assayed. The less common salts will be processed to quinine sulfate or hydrochloride. The materials needed are bulk cinchona salts and alkaloids, tablets, capsules and pills, quinine, quinidine, cinchonine and cinchonidine. Do not send preparations of quinine or other cinchona derivatives in combination with other medicinal agents, ampuls and parenteral medication, liquid preparations or quinine and urea hydrochloride, quinine and urethane, quinine bismuth iodide, elixir iron, quinine and strychnine and similar preparations. The armed forces need all available quinine. Any contribution, no matter how small, will be useful, the need is urgent.

NATIONAL NURSING COUNCIL NEEDS COOPERATION OF PHYSICIANS

The National Nursing Council for War Service, which represents the voluntary, professional nursing organizations in the total war program, urges every physician in the country to lend his help and support to the current nationwide effort to locate all graduate registered nurses. A second national inventory of nurses, a follow-up on the inventory of 1941, was begun in January 1943. To date (February 25) responses from nearly 50 per cent of the nurses in the country have been reported. To help bring in responses from the remaining 50 per cent, physicians are asked to

1 Encourage the nurses who may be associated with them, especially the nurses in their employ, to respond without delay to the post card questionnaires sent to them by the special

state agent of the United States Public Health Service in January of this year.

2 Urge nurses they may know who have not received questionnaires (many physicians' wives who are nurses have failed to receive them) to request cards from the special agent in their states. If they do not know the agent's address, the National Nursing Council for War Service, 1790 Broadway, New York, will forward their requests.

Information provided by the inventory will furnish the basis of operation for the nursing supply and distribution unit now being formed in the War Manpower Commission. The purpose of the unit, as the name implies, is to determine the availability of nurses for local, state and national emergencies and to aid in the equitable distribution of nurses, so that the nursing needs of the armed forces and of civilians will be adequately met. This distribution will be on a voluntary, not a compulsory, basis. The inventory is being conducted by the United States Public Health Service and has the approval of the National Nursing Council for War Service, the War Manpower Commission and the Health and Medical Committee, Office of Defense Health and Welfare Services, Federal Security Agency.

INDUSTRY AND THE MEDICAL PROFESSION

Increased utilization of medical services by industry has been so rapid that training and experience have frequently had to be overlooked. Complaint is made that personnel without proper qualifications assume responsibilities beyond their professional capacity. Faulty x-ray interpretation by doctors and technicians and medical-surgical treatment by unsupervised nurses and aides lead to much dissatisfaction. Continued, unwarranted performances of this type hardly conform with standards of acceptable industrial medical procedure recommended by the Council on Industrial Health.¹ Until recently, management has been unable to secure dependable advice in the development of industrial health service. Improved organization in the state and county medical societies and in the state and local health departments will do much to overcome this lack of satisfactory rapport between medicine and industry. However, industry has sometimes misconstrued its own responsibility. If progress toward better working conditions and healthier employees is to occur, management must make industrial health service professionally worth while. The population groups involved and the results in terms of community betterment and well-being are so great that industrial health service should attract the best professional minds and equipment. Advancement will occur in direct proportion to the willingness of management and insurance to take industrial medical service off the bargain counter. Complaint is also received that physicians in industry occasionally use industrial connections to enhance private practice. The use of direct or indirect pressure on industrial workers by personnel in the industrial medical department in respect to management of any nonoccupational disorder is decidedly unfair.

MEDICINE AND THE WAR

In this section of *The Journal* each week will appear official notices by the Committee on War Participation of the American Medical Association, announcements by the Surgeon Generals of the Army, Navy and Public Health Service, and other governmental agencies dealing with medicine and the war and such other information and announcements as will be useful to the medical profession

ARMY

PROCEDURE OF PROCESSING PHYSICIANS, DENTISTS AND VETERINARIANS IN THE FIELD

The War Department Service of Supply, Officer Procurement Service, issued the following memorandum under date of February 27, covering the procedure for processing physicians, dentists and veterinarians in the field

NOTE—This memorandum both restates prior instructions and contains new instructions. Immediate attention to its provisions is essential to field office work.

1 *Scope of Memorandum Rescission of Prior Instructions*—(a) This memorandum states the procedure under which Officer Procurement Service will assist the Surgeon General in processing physicians, dentists and veterinarians for appointment as officers in the Army of the United States. The procedure here stated is approved for the processing and appointment of physicians, dentists and veterinarians only and does not apply to the processing and appointment of candidates for any other position for the Surgeon General.

(b) Prior instructions still in effect have been consolidated in this memorandum. Accordingly FT-15 (January 13) and attached memorandum, FT-17 (January 18), FT-24 (January 27), FT-29 (February 11), FT-31 (February 17), FT-33 (February 22) and all other instructions in this connection are hereby rescinded.

2 *The Surgeon General's 1943 Recruiting Program*—(a) The 1943 program of the Surgeon General for the appointment of qualified individuals from civil life in the Medical Corps, Dental Corps and Veterinary Corps includes not only physicians, dentists and veterinarians established in their communities but also medical interns and residents of hospitals. This program is as follows:

	Hospital Interns and Residents	Others	Total
Physicians	3 000 approx	6 900	9 900
Dentists	0 imately	4 800	4 800
Veterinarians	0	900	900
	3 000 appr	12 600	15 600

The requirements of the Air Surgeon are included in the foregoing.

(b) The monthly objective for appointments of those other than from the hospital intern and resident category is as follows:

Physicians Medical Corps	575
Dentists Dental Corps	400
Veterinarians, Veterinary Corps	75

1 050 per month

(c) The objective for appointments from the hospital intern and resident category cannot be readily stated in monthly quotas. Most internships terminate about June 30. Whereas small numbers of interns and residents may be available in all months, the bulk of the processing in this category should come during May, June and July. The number of hospitals in the eastern part of the United States being greater than elsewhere, the number of cases in this category to be processed in the East will be proportionately greater.

(d) All cases included within the Surgeon General's program here outlined will be dealt with in accordance with the procedure stated in this memorandum.

NOTE—During years prior to 1943 the Medical Department commissioned many students and interns in the Medical Administrative Corps A U S. These individuals have remained on inactive duty status pending completion of their medical education. Also medical dental and veterinary students and interns who have previously been commissioned

and now hold appointments in the Officers Reserve Corps in other branches have been similarly deferred from active duty. During 1943 the existing commissions of these individuals may be terminated at their own request under certain circumstances and when qualified these individuals may be appointed as officers in the Medical Dental or Veterinary Corps. Officer Procurement Service has no processing or other function in regard to such appointments. The appointment of individuals referred to in this note will be handled by the individuals directly with the Surgeon General. Inquiries in regard to such appointments should be referred to the Procurement Section, Military Personnel Division, Office of the Surgeon General of the Army, 1815 H Street NW, Washington, D C.

3 *States from Which Physicians, Dentists and Veterinarians Will Be Recruited*—(a) (1) Physicians will be procured in the following states: California, Colorado, Connecticut, District of Columbia, Illinois, Iowa, Maryland, Massachusetts, Minnesota, Missouri, Nebraska, Nevada, New Hampshire, New Jersey, New York, Ohio, Oregon, Pennsylvania, Rhode Island, Vermont and Wisconsin.

(2) The following states have already contributed more physicians to the armed forces than the sum of their 1942 and 1943 quotas and will not be called on to furnish any more physicians, except interns and residents and except special cases for specific position vacancies, during 1943: Alabama, Arizona, Delaware, Georgia, Idaho, Kentucky, Louisiana, Mississippi, New Mexico, North Carolina, South Carolina, Tennessee, Texas, West Virginia and Wyoming.

(3) In states not listed in either a (1) or (2) there will be at present no procurement of physicians, except interns and residents and except special cases for specific position vacancies.

(b) There will be no procurement of dentists, except special cases for specific position vacancies in Alabama, Arizona, Arkansas, Delaware, Florida, Georgia, Kentucky, Louisiana, Mississippi, New Mexico, North Carolina, Oklahoma, South Carolina, Tennessee, Texas and Virginia.

(c) There are no restrictions at present on recruiting veterinarians.

4 *Function of Officer Procurement Service*—(a) Officer Procurement Service will process the papers of all physicians, dentists and veterinarians whose availability for commissioning in the Army of the United States has been determined by the War Manpower Commission (see paragraph 5) and will transmit to the Secretary of War's Personnel Board requests for appointment of such individuals, submitted by the Surgeon General.

(b) Officer Procurement Service has no function to perform until an officer procurement district office has received from the War Manpower Commission a determination of availability of a physician, dentist, or veterinarian. See paragraph 6.

(c) The district office will interview each candidate for character, integrity, reputation and qualification for commissioning as an officer. The investigation will be limited to these subjects and will not extend to an appraisal of professional qualifications. A form OPB 2 (completed as to the side containing the interviewer's remarks) will be included with the candidate's file when forwarded to the Surgeon General. (The other side of the form need not be completed.)

(d) The Surgeon General has discontinued all medical officer recruiting boards. In certain service commands officer procurement district offices may find it desirable to arrange in investigating candidates, for assistance from the chief of the medical branch in the service command.

(e) District offices will not forward to the Surgeon General any papers concerning unavailable physicians, dentists or veterinarians except as requested by higher authority. Questionnaires

and related papers of unavailable physicians, dentists and veterinarians, if any, should be retained in the District Office's inactive file pursuant to FP-14, Feb. 3, 1943, paragraph 6 c.

(f) Inquiries to a district office by physicians, dentists and veterinarians concerning whom no determination of availability has been received by the district office should be referred to the appropriate state chairman, Procurement and Assignment Service, War Manpower Commission. See paragraph 5.

5 Function of War Manpower Commission.—(a) The War Manpower Commission functions through its Procurement and Assignment Service. This service determines whether a physician, dentist or veterinarian is available for commissioning in the armed forces of the United States. No physician, dentist or veterinarian may be processed for appointment or appointed in the Army of the United States unless and until his availability has been so determined.

(b) In each state the Procurement and Assignment Service has set up three state chairmen: medical, dental, veterinary. Attached hereto marked Tab A is a schedule showing for each state the authorized chairmen and their co-chairmen and vice chairmen, if any (herein called state P and A chairmen).

(c) Each state P and A chairman prepares a monthly quota list of physicians, dentists and veterinarians (as the case may be) who are apparently suitable and who are determined to be available for commissioning in the Army of the United States. To each individual so listed the central office of the Procurement and Assignment Service sends a communication inviting him to apply for service with the armed forces (opportunity being afforded to indicate on the inclosed reply card preference for Army, Navy or Medical Department of the Air Forces). The reply cards are sent by the potential applicants to the appropriate state P and A chairmen.

(d) On receipt from time to time by the state P and A chairmen of such reply cards they give to Officer Procurement Service the notice of availability provided in paragraph 6.

6 Notice of Availability Given by State P and A Chairmen.—(a) Notice of availability of a particular physician, dentist or veterinarian within the jurisdiction of a state P and A chairman will be given by such chairman to Officer Procurement Service on form 97 ('Availability Clearance Form') or some similar form in duplicate. Preference for service with the Medical Department of the Army, Air Forces will be plainly indicated on form 97 by the state chairman.

(b) Such notice of availability will be given by the state chairman direct to the designated officer procurement district office in accordance with the schedule shown on Tab B attached. This schedule has been set up to meet the convenience of the Surgeon General and must be explicitly followed. A designated district office which receives a notice of availability may forward it to another district office for necessary action (for example, New York City may forward to Albany or Buffalo).

(c) In the event that a notice is received by an officer procurement district office signed by other than the authorized state chairman, his alternate or a person duly authorized by such state chairman to give notice in his behalf, the office will return such notice to the state chairman before taking action, with an explanation that only notices bearing authorized signatures can be honored.

(d) No action will be taken by an officers' procurement district office in any case until receipt by it of a properly executed form 97, evidencing determination of the individual's availability. Form 97 indicating unavailability should be returned by district offices to the proper state P and A chairman without action.

(e) Attention is invited to the provision of AR 605-10, paragraph 6.

An officer of the Army of the United States must at the time of appointment be a citizen of the United States or of the Philippine Islands or a citizen of a cobelligerent or friendly country who otherwise possesses the same qualifications as a citizen of the United States.

Any notice of availability of a physician, dentist or veterinarian who does not comply with this provision should be returned to the proper state P and A chairman without action.

7 Processing Procedure.—(a) On receipt of notice of availability in regard to an individual physician, dentist or veterinarian the officer procurement district office will promptly

contact the individual and arrange for an interview. At the same time the individual should be advised of the papers which he must furnish and the steps which he must take. See paragraph 8.

(b) In areas where considerable travel is involved, district offices will endeavor to schedule visits of their officers through such areas so that applicants may be interviewed at or near their home cities. District offices are authorized to cooperate with state P and A chairmen so as to facilitate the scheduling of such visits.

(c) The individual will be requested by the district office to complete all papers and take all steps required of him within fourteen days of the date of such request.

(d) If no reply is received from a candidate or if a candidate declines to act as indicated, a report thereon will be transmitted by the officer procurement district office to the state chairman.

(e) As soon as the candidate's processing is completed, the fully processed papers will be forwarded by air mail by the field office direct to:

Procurement Section
Military Personnel Division
Office of the Surgeon General of the Army
1618 H Street N.W., Washington, D. C.

It is essential to carrying forward the Surgeon General's program that such completed papers be sent direct and not through channels.

(f) If the completed papers cannot be forwarded within two weeks after the date of receiving the notification of availability, the district office will advise the state chairman of the exact status of processing. The state chairman is charged with responsibility for making further inquiry of the candidate. In the event that the district office is about to complete the processing at the end of the fourteenth day of the period, such advice to the state chairman may be omitted.

(g) If a candidate's papers on submission by the Surgeon General to Officer Procurement Service on a form OPS 3 are incomplete, they will be returned to the appropriate district office attached to a form OPS 2. When a district office receives such papers, it will take the action necessary to complete the same. On completion the papers will be returned to Chief Field Operations Branch, Officer Procurement Service, Washington, D. C. This is the only instance in which a district office sends papers concerning physicians, dentists and veterinarians direct to Washington headquarters of Officer Procurement Service.

(h) The decision as to grade and appointment to be recommended for each candidate rests with the Surgeon General.

8 Papers to be Furnished by Candidates.—(a) The completed file of each physician, dentist or veterinarian forwarded by a district office to the Surgeon General pursuant to paragraph 7 d, should include:

- (1) WD AGO Form 0850 in duplicate with passport size photo attached and each question fully answered.
- (2) WD AGO Form 1782 in duplicate (Classification Questionnaire of Medical Department Reserve Officers).
- (3) WD AGO Form 61 in triplicate.
- (4) Affidavit of physical defect in duplicate if required.
- (5) Form OPB 2 (OPS interviewer's report) in duplicate. See paragraph 4 c.
- (6) Form OPB 5 (certificate of inspection of naturalization papers if candidate is not a citizen by birth or has lost citizenship) in duplicate.
- (7) Federal employee — written release from federal employment signed by responsible executive.

(b) In addition to the papers listed in a, the completed file of each physician, dentist and veterinarian who is a graduate of a foreign (other than Canadian) medical school should include the following or, if not available, a detailed explanation in lieu thereof, with request for a waiver:

NOTE.—Canadian medical, dental and veterinary schools are not deemed foreign medical schools.

(1) Transcript of preprofessional education, which must be equivalent to the requirements for admission to an approved American medical, dental or veterinary school (with certified translation).

(2) Resume of the credit hours and grades received in each course at professional school and if more than one professional school was attended, full particulars in regard thereto.

(3) Photostat of diploma which was awarded after four years' academic instruction in medicine, dentistry or veterinary medicine (with certified translation)

(4) Photostat of license to practice in a state, territory or the District of Columbia (such licensure cannot be waived) or certification by an army officer on active duty that he has seen the applicant's license, also a license or registration authorizing practice in the country where professional education was obtained

(5) Certificate of approved internship of not less than one year's duration in the case of physicians

(6) If the candidate is a diplomate of the National Board of Medical Examiners, or if accepted by said board for examination, substantiating evidence

(c) In addition to the papers listed in *a*, the completed file of each physician who is a graduate of a nonapproved medical school (Chicago Medical School Middlesex College of Medicine and Surgery and Cincinnati Eclectic School of Medicine) should include the following

(1) Letter from the dean of his medical school verifying the fact that he has satisfactorily completed a four year course of regular medicine and has been granted an M.D. degree

(2) Letter from the superintendent of a hospital verifying at least one year of rotating internship on the part of the applicant

(3) Photostat of, or certification by, an army officer on active duty that he has seen the applicant's license to practice medicine in a state, territory or the District of Columbia (Such licensure cannot be waived)

(4) Letter from three physicians who are graduates of an approved medical school and are practicing in the county where the applicant resides, stating that they know the applicant to be engaged in the ethical practice of medicine. Such letters should state the writer's school and year of graduation, in addition to information concerning applicant's professional qualifications

(5) Evidence of membership in his local county medical society or a letter from the secretary of the district or county medical society, substantially as follows

Dr	of	Place	
society as a graduate of		Date	
in			is known to this
practice of medicine in			Medical School located
having been licensed by this state since			He is engaged in the
so far as is known an ethical practitioner of medicine			He is
eligible to apply for membership in the			Medical
Society if he had been in practice for	years		Having attained
such membership he would be accredited to the			
District (County) Medical Society			
Signed			
Secretary	(District) (County)		
Medical Society			

(The applicant should bring his diploma and certificate of licensure to the district or county secretary when requesting such a letter)

(d) In addition to the papers listed under *a* and otherwise required under *b* or *c*, the completed file of each physician, dentist or veterinarian who is a Canadian citizen should include the following

(1) Evidence that he has applied for his first papers as an American citizen

(2) A release from the Canadian legation

(c) In addition to the papers listed under *a* and otherwise required under *b* or *d*, the completed file of a dentist or veterinarian should include the following

(1) Photostatic copy or certified evidence of license to practice his profession for the current or the ensuing year in a state, territory or the District of Columbia

(2) For an individual who has graduated from dental or veterinary school in 1942 or 1943 either a license to practice or a photostatic copy of diploma or certificate of the dean of the appropriate school as to graduation

9 *Nonrequirement of Release from Selective Service Classification II-A, II-B, or III-B*—Notwithstanding the provisions of AR-605-10, Dec 30, 1942, paragraph 7 *j* to the effect that "No civilian, of any age, will be appointed if classified as II-A, II-B, or III-B unless released from such classification by his local draft board," no such release need be obtained in the case of a physician, dentist or veterinarian whose availability has been determined by the War Manpower Commission (Procurement and Assignment Service). Neither is it required that a draft status certificate be furnished in regard to a physician, dentist, or veterinarian

10 *Weekly Reports*—(a) Each officer procurement district office will submit to Washington headquarters of Officer Procurement Service, as of Thursday night, commencing with March 4 1943, a report of all cases handled under the foregoing procedure, in the form attached hereto and marked Tab C

(b) In the March 4 report district offices will break down the prior cumulative aggregates of physicians, dentists and veterinarians into the three separate categories

(c) The accuracy of the figures in the weekly report will be verified by the district office before submission, by checking as indicated on the form (Tab C)

(d) Notices of availability concerning physicians, dentists and veterinarians which are received by officer procurement districts designated to receive them from state chairmen (see Tab B), and which are forwarded to other officer procurement districts for action, will not be included in the weekly report of the office forwarding them. Such requests will be included in the report of the office which does the processing

COLLECT 150,000 GRAINS OF QUININE

In response to the government's appeal for quinine for the treatment of American troops in malaria infected areas (THE JOURNAL, Oct 3, 1942 p 377) the eleven Illinois state mental hospitals have collected from their supplies nearly 150,000 grains. Dr Harry R Hoffman, director of the Neuropsychiatric Institute University of Illinois School of Medicine, Chicago, announced on March 5. Dr Hoffman, who acted as collecting agent in the drive for quinine for the state of Illinois indicated that the supplies in these mental hospitals presumably were acquired to be used in the artificial fever therapy of dementia paralytica the quinine being used to cure the malaria in patients after it had served its purpose. This method is not now so frequently employed, as electrical means of causing a better controlled fever have been introduced. The Philadelphia College of Pharmacy and Chemistry Forty-Third Street and Woodland and Kingsessing avenues Philadelphia was authorized by the War Production Board to act as an assaying depot for any unopened packages of quinine compounds that are contributed by pharmacists. All such packages should be addressed to the Quinine Pool at the foregoing address.

DEDICATION OF THE PERCY L JONES GENERAL HOSPITAL

The U S Army Percy L Jones General Hospital at Battle Creek, Mich., was formally dedicated February 22. Among those present were the Honorable Harry F Kelly, governor of Michigan, Major Gen Henry S Aurand, commanding officer of the Sixth Service Command, with headquarters in Chicago. Major Gen James C Magee, Washington D C Surgeon General of the Army, Brig Gen John M Willis commander of the medical replacement training center at Camp Grant Illinois, Col Joseph E Bastion chief of the medical branch of the Sixth Service Command, Chicago. Col Norman T Kirk commanding officer of the hospital, Dr John Harvey Kellogg founder and for many years director of the Battle Creek Sanitarium. Mrs Percy L Jones and her daughter Mrs Charles Siegel of Erie Pa. and many other distinguished guests. The remodeling of the hospital buildings which a few months ago were those of the Battle Creek Sanitarium is practically complete and about 400 patients have been admitted including 175 sick and wounded soldiers from the Pacific theater of war. This hospital was named in honor of the late Col Percy L Jones for many years a distinguished member of the U S

and related papers of unavailable physicians, dentists and veterinarians, if any, should be retained in the District Office's inactive file pursuant to FP-14 Feb. 3, 1943, paragraph 6 c.

(f) Inquiries to a district office by physicians, dentists and veterinarians concerning whom no determination of availability has been received by the district office should be referred to the appropriate state chairman, Procurement and Assignment Service, War Manpower Commission. See paragraph 5.

5 Function of War Manpower Commission.—(a) The War Manpower Commission functions through its Procurement and Assignment Service. This service determines whether a physician, dentist or veterinarian is "available" for commissioning in the armed forces of the United States. No physician, dentist or veterinarian may be processed for appointment or appointed in the Army of the United States unless and until his availability has been so determined.

(b) In each state the Procurement and Assignment Service has set up three state chairmen: medical, dental, veterinary. Attached hereto marked Tab A, is a schedule showing for each state the authorized chairmen, and their co-chairmen and vice chairmen, if any (herein called "state P and A chairmen").

(c) Each state P and A chairman prepares a monthly quota list of physicians, dentists and veterinarians (as the case may be) who are apparently suitable and who are determined to be available, for commissioning in the Army of the United States. To each individual so listed the central office of the Procurement and Assignment Service sends a communication inviting him to apply for service with the armed forces (opportunity being afforded to indicate on the inclosed reply card preference for Army, Navy or Medical Department of the Air Forces). The reply cards are sent by the potential applicants to the appropriate state P and A chairman.

(d) On receipt from time to time by the state P and A chairmen of such reply cards, they give to Officer Procurement Service the notice of availability provided in paragraph 6.

6 Notice of Availability Given by State P and A Chairmen.—(a) Notice of availability of a particular physician, dentist or veterinarian within the jurisdiction of a state P and A chairman will be given by such chairman to Officer Procurement Service on form 97 (Availability Clearance Form) or some similar form in duplicate. Preference for service with the Medical Department of the Army, Air Forces will be plainly indicated on form 97 by the state chairman.

(b) Such notice of availability will be given by the state chairman direct to the designated officer procurement district office in accordance with the schedule shown on Tab B attached. This schedule has been set up to meet the convenience of the Surgeon General and must be explicitly followed. A designated district office which receives a notice of availability may forward it to another district office for necessary action (for example, New York City may forward to Albany or Buffalo).

(c) In the event that a notice is received by an officer procurement district office signed by other than the authorized state chairman, his alternate or a person duly authorized by such state chairman to give notice in his behalf, the office will return such notice to the state chairman before taking action, with an explanation that only notices bearing authorized signatures can be honored.

(d) No action will be taken by an officers' procurement district office in any case until receipt by it of a properly executed form 97, evidencing determination of the individual's availability. Form 97 indicating unavailability should be returned by district offices to the proper state P and A chairman without action.

(e) Attention is invited to the provision of AR 605-10, paragraph 6.

An officer of the Army of the United States must at the time of appointment be a citizen of the United States or of the Philippine Islands or a citizen of a cobelligerent or friendly country who otherwise possesses the same qualifications as a citizen of the United States.

Any notice of availability of a physician, dentist or veterinarian who does not comply with this provision should be returned to the proper state P and A chairman without action.

7 Processing Procedure.—(a) On receipt of notice of availability in regard to an individual physician, dentist or veterinarian, the officer procurement district office will promptly

contact the individual and arrange for an interview. At the same time the individual should be advised of the papers which he must furnish and the steps which he must take. See paragraph 8.

(b) In areas where considerable travel is involved, district offices will endeavor to schedule visits of their officers through such areas so that applicants may be interviewed at or near their home cities. District offices are authorized to cooperate with state P and A chairmen so as to facilitate the scheduling of such visits.

(c) The individual will be requested by the district office to complete all papers and take all steps required of him within fourteen days of the date of such request.

(d) If no reply is received from a candidate or if a candidate declines to act as indicated, a report thereon will be transmitted by the officer procurement district office to the state chairman.

(e) As soon as the candidate's processing is completed, the fully processed papers will be forwarded by air mail by the field office direct to:

Procurement Section
Military Personnel Division
Office of the Surgeon General of the Army
1618 H Street N.W. Washington, D. C.

It is essential to carrying forward the Surgeon General's program that such completed papers be sent direct and not through channels.

(f) If the completed papers cannot be forwarded within two weeks after the date of receiving the notification of availability, the district office will advise the state chairman of the exact status of processing. The state chairman is charged with responsibility for making further inquiry of the candidate. In the event that the district office is about to complete the processing at the end of the fourteenth day of the period, such advice to the state chairman may be omitted.

(g) If a candidate's papers, on submission by the Surgeon General to Officer Procurement Service on a form OPS-1 are incomplete they will be returned to the appropriate district office attached to a form OPS-2. When a district office receives such papers, it will take the action necessary to complete the same. On completion the papers will be returned to Chief Field Operations Branch, Officer Procurement Service, Washington, D. C. This is the only instance in which a district office sends papers concerning physicians, dentists and veterinarians direct to Washington headquarters of Officer Procurement Service.

(h) The decision as to grade and appointment to be recommended for each candidate rests with the Surgeon General.

8 Papers to be Furnished by Candidates.—(a) The completed file of each physician, dentist or veterinarian forwarded by a district office to the Surgeon General pursuant to paragraph 7 d should include:

- (1) WD AGO Form 0950 in duplicate with passport size photo attached and each question fully answered.
- (2) WD ACO Form 178.2 in duplicate (Classification Questionnaire of Medical Department Reserve Officers).
- (3) WD AGO Form 61 in triplicate.
- (4) Affidavit of physical defect in duplicate if required.
- (5) Form OPB-2 (OPS interviewer's report) in duplicate. See paragraph 4 c.
- (6) Form OPB-5 (certificate of inspection of naturalization papers if candidate is not a citizen by birth or has lost citizenship) in duplicate.
- (7) Federal employee — written release from federal employment signed by responsible executive.

(b) In addition to the papers listed in a, the completed file of each physician, dentist and veterinarian who is a graduate of a foreign (other than Canadian) medical school should include the following or, if not available, a detailed explanation in lieu thereof, with request for a waiver:

NOTE—Canadian medical, dental and veterinary schools are not deemed foreign medical schools.

(1) Transcript of preprofessional education, which must be equivalent to the requirements for admission to an approved American medical, dental or veterinary school (with certified translation).

(2) Resume of the credit hours and grades received in each course at professional school, and if more than one professional school was attended full particulars in regard thereto.

(3) Photostat of diploma which was awarded after four years' academic instruction in medicine, dentistry or veterinary medicine (with certified translation)

(4) Photostat of license to practice in a state, territory or the District of Columbia (such licensure cannot be waived) or certification by an army officer on active duty that he has seen the applicant's license, also a license or registration authorizing practice in the country where professional education was obtained

(5) Certificate of approved internship of not less than one year's duration in the case of physicians

(6) If the candidate is a diplomate of the National Board of Medical Examiners, or if accepted by said board for examination, substantiating evidence

(c) In addition to the papers listed in *a*, the completed file of each physician who is a graduate of a nonapproved medical school (Chicago Medical School, Middlesex College of Medicine and Surgery and Cincinnati Eclectic School of Medicine) should include the following

(1) Letter from the dean of his medical school verifying the fact that he has satisfactorily completed a four year course of regular medicine and has been granted an M.D. degree

(2) Letter from the superintendent of a hospital verifying at least one year of rotating internship on the part of the applicant

(3) Photostat of, or certification by, an army officer on active duty that he has seen the applicant's license to practice medicine in a state, territory or the District of Columbia (Such licensure cannot be waived)

(4) Letter from three physicians who are graduates of an approved medical school and are practicing in the county where the applicant resides, stating that they know the applicant to be engaged in the ethical practice of medicine. Such letters should state the writer's school and year of graduation, in addition to information concerning applicant's professional qualifications

(5) Evidence of membership in his local county medical society or a letter from the secretary of the district or county medical society, substantially as follows

Dr	of	Place	is known to this
society as a graduate of		Date	Medical School located
in			He is engaged in the
practice of medicine in			He is
having been licensed by this state since			so far as is known an ethical practitioner of medicine
so far as is known an ethical practitioner of medicine			He would be
eligible to apply for membership in the			Medical
Society if he had been in practice for	years		Having attained
such membership he would be accredited to the			
District (County) Medical Society			
Signed		(District) (County)	
Secretary		Medical Society	

(The applicant should bring his diploma and certificate of licensure to the district or county secretary when requesting such a letter)

COLLECT 150,000 GRAINS OF QUININE

In response to the government's appeal for quinine for the treatment of American troops in malaria infected areas (THE JOURNAL, Oct 3 1942 p 377) the eleven Illinois state mental hospitals have collected from their supplies nearly 150,000 grains. Dr Harry R. Hoffman, director of the Neuropsychiatric Institute, University of Illinois School of Medicine, Chicago, announced on March 5 Dr Hoffman, who acted as collecting agent in the drive for quinine for the state of Illinois, indicated that the supplies in these mental hospitals presumably were acquired to be used in the artificial fever therapy of dementia paralytica, the quinine being used to cure the malaria in patients after it had served its purpose. This method is not now so frequently employed as electrical means of causing a better controlled fever have been introduced. The Philadelphia College of Pharmacy and Chemistry, Forty-Third Street and Woodland and Kingsessing avenues, Philadelphia, was authorized by the War Production Board to act as an assaying depot for any unopened packages of quinine compounds that are contributed by pharmacists. All such packages should be addressed to the Quinine Pool at the foregoing address.

(d) In addition to the papers listed under *a* and otherwise required under *b* or *c*, the completed file of each physician, dentist or veterinarian who is a Canadian citizen should include the following

(1) Evidence that he has applied for his first papers as an American citizen

(2) A release from the Canadian legation

(c) In addition to the papers listed under *a* and otherwise required under *b* or *d*, the completed file of a dentist or veterinarian should include the following

(1) Photostatic copy or certified evidence of license to practice his profession for the current or the ensuing year in a state, territory or the District of Columbia

(2) For an individual who has graduated from dental or veterinary school in 1942 or 1943 either a license to practice or a photostatic copy of diploma or certificate of the dean of the appropriate school as to graduation

9 *Nonrequirement of Release from Selective Service Classification II-A, II-B, or III-B*—Notwithstanding the provisions of AR 605-10, Dec 30, 1942, paragraph 7 *j*, to the effect that "No civilian, of any age, will be appointed if classified as II-A, II-B, or III-B unless released from such classification by his local draft board," no such release need be obtained in the case of a physician, dentist or veterinarian whose availability has been determined by the War Manpower Commission (Procurement and Assignment Service). Neither is it required that a draft status certificate be furnished in regard to a physician, dentist, or veterinarian

10 *Weekly Reports*—(a) Each officer procurement district office will submit to Washington headquarters of Officer Procurement Service, as of Thursday night, commencing with March 4 1943, a report of all cases handled under the foregoing procedure, in the form attached hereto and marked Tab C

(b) In the March 4 report district offices will break down the prior cumulative aggregates of physicians, dentists and veterinarians into the three separate categories

(c) The accuracy of the figures in the weekly report will be verified by the district office before submission, by checking as indicated on the form (Tab C)

(d) Notices of availability concerning physicians, dentists and veterinarians which are received by officer procurement districts designated to receive them from state chairmen (see Tab B), and which are forwarded to other officer procurement districts for action will not be included in the weekly report of the office forwarding them. Such requests will be included in the report of the office which does the processing

DEDICATION OF THE PERCY L JONES GENERAL HOSPITAL

The U S Army Percy L Jones General Hospital at Battle Creek, Mich., was formally dedicated February 22. Among those present were the Honorable Harry F. Kelly, governor of Michigan, Major Gen. Henry S. Aurand, commanding officer of the Sixth Service Command, with headquarters in Chicago, Major Gen. James C. Magee, Washington D. C., Surgeon General of the Army, Brig. Gen. John M. Willis, commander of the medical replacement training center at Camp Grant, Illinois, Col. Joseph E. Bastion, chief of the medical branch of the Sixth Service Command, Chicago, Col. Norman T. Kirk, commanding officer of the hospital, Dr. John Harvey Kellogg, founder and for many years director of the Battle Creek Sanitarium, Mrs. Percy L. Jones and her daughter, Mrs. Charles Siegel of Erie, Pa., and many other distinguished guests. The remodeling of the hospital buildings which a few months ago were those of the Battle Creek Sanitarium is practically complete and about 400 patients have been admitted, including 175 sick and wounded soldiers from the Pacific theater of war. This hospital was named in honor of the late Col. Percy L. Jones for many years a distinguished member of the U S

Army Medical Corps During the ceremonies an oil painting of Colonel Jones was unveiled by his widow. Following the dedication, a reception in honor of Mrs. Jones was held in the Officer's Club. The *Battle Creek Enquirer and News* issued a special section pertaining to the hospital and the dedication. Additional information concerning the hospital was published in *THE JOURNAL*, Dec. 12, 1942, page 1220.

IN MEMORY OF FLIGHT SURGEONS

In memory of deceased flight surgeons, the memorial window which has been placed in the post chapel at the School of Aviation

Memorial window in post chapel at School of Aviation Medicine, Randolph Field, Texas.

tion Medicine, Randolph Field, Texas, will be dedicated April 2. The window was presented by more than three hundred medical officers in the class of '42-F of Aviation Medical Examiners.

ARMY PERSONALS

Major Guy W. Harlow, Medical Administrative Corps, stationed at the Medical Replacement Training Center, Camp Barkeley, Texas, has been promoted to the rank of lieutenant colonel. Lieut. Col. Harlow has served eighteen years in the Army and was first commissioned as a second lieutenant in 1933. His family home is in Newark, Ohio.

PRESBYTERIAN HOSPITAL (CHICAGO) UNIT

Although U. S. Army General Hospital No. 13, the Chicago Presbyterian Hospital Unit, has not been called to active duty as a unit, the administrative officers, the 350 enlisted men and more than two thirds of its nurses are now in army camps and hospitals. The enlisted personnel reported to Camp Grant in December and to Camp Robinson in January, and the following medical officers had already reported for duty at Camp Robinson at the time the February bulletin of the Presbyterian Hospital of the City of Chicago was published: Lieut. Col. Homer K. Nicoll, chief of medical service, Majors Linden J. Wallner, Cyril V. Crane and George C. Turner, Capt. John Tysell and George Pelkey, and Lieuts. A. Deo Klein, DDS, and Robert K. Stockton, DDS. The commanding officer of the hospital unit is Col. Lyle S. Powell, and the administrative officer in charge of enlisted personnel is Major William T. Willis.

HOSPITALIZATION OF WOUNDED FROM OVERSEAS

The War Department has promulgated a hospitalization distribution plan for patients returning to the United States from overseas providing for transfer to general hospitals in the interior of officers, army nurses, warrant officers, enlisted men, dietitians, physical therapy aides, members of the WAACs, contract surgeons and other military personnel who are to be kept under further observation and treatment. While such transfers will not be made when a break in treatment might retard recovery of the patient, the general policy will be to transfer to general hospitals designated for special cases those persons who require special treatment and to send patients who will be discharged for disability or who require prolonged hospitalization to a general hospital in the vicinity of their homes. Such transfers will be made, generally, when there are 25 or more such patients.

"HEALTH BOMB" FOR PROTECTION AGAINST INSECTS

With the guidance of the Surgeon General's Office of the Army, Westinghouse engineers have developed a simple throw-away metal dispenser, about the size of a tin can, which discharges a mist that is fatal to mosquitoes and flies yet harmless to men and thus arms our fighting men in tropical jungles with a new weapon against malaria and yellow fever. Each dispenser or health bomb is loaded with 1 pound of a liquid insecticide developed by a chemist in the Department of Agriculture, Dr. Lyle D. Goodhue. The fine mist released can be turned off and on at will. Only three seconds is required to fumigate a pup tent, and one dispenser will fumigate two hundred and forty pup tents, fifty grant bombers, or 150,000 cubic feet of space.

The facilities of the Westinghouse plants are being expanded in order to be able to supply dispensers at a rate of ten thousand a day. This dispenser makes unnecessary cumbersome spraying equipment. The insecticide used is effective also against ants and cockroaches, and experiments are under way to establish its effectiveness against still other forms of insect life.

CAPTAIN FURBECK GRADUATES AT CARLISLE

Capt. George Nelson Furbeck, a native of Albany, N. Y., and a resident of Mexico, graduated in the twentieth officers' class at the Medical Field Service School, Carlisle Barracks, Pa., February 25. Captain Furbeck was the first United States citizen to graduate from the National University of Mexico Medical School. He interned at the General Hospital in Mexico City, was admitted to practice in accordance with regulations in Mexico and in 1932 came to the United States for a year's internship in Charity Hospital, New Orleans. In 1933 he returned to Mexico City, where he practiced medicine until the attack on Pearl Harbor, when he volunteered and was commissioned a captain in the U. S. Army. Captain Furbeck plans after the war to return to practice in Mexico City, where his wife and daughters reside.

PUBLIC HEALTH SERVICE

THE RAPID TREATMENT CENTER PROGRAM

To clarify the policies and responsibilities of the United States Public Health Service in the new nationwide system of rapid treatment centers for persons infected with venereal disease, a special edition of the *VD War Letter* was issued, March 1.

The rapid treatment center program, it is said, is an outgrowth of the national venereal disease control program begun in 1938 and has been developed by state health departments, United States Public Health Service, the Office of Defense Health and Welfare Services and the Federal Works Agency as a direct effort to combat a wartime threat to our national strength.

The basic responsibility of the Public Health Service is to provide consultation service to other agencies cooperating in the program and to furnish specially trained physicians, nurses and technical personnel to operate the centers. More than thirty centers will be in operation by the end of 1943.

Federal funds are made available for the establishment of the centers under the Lanham Act, which is administered by the Federal Works Agency. Each state project approved by Federal Works Agency is subject to prior review and certification by the U S Public Health Service.

The establishment of hospital facilities to which state health authorities may send a large number of infected persons, with the assurance that they will receive prompt effective treatment will mean real progress in the ultimate eradication of venereal diseases as well as immediate assistance to wartime control. Federal, state and local health authorities will gain valuable experience in the administration of this type of institution. Finally, by applying the newer technics in the treatment of syphilis and gonorrhea, under the best medical supervision available in this country, we shall be able to demonstrate the effectiveness of these treatment methods on a large scale in order that the entire medical profession may profit by the experience thus accumulated.

Public Health Service physicians assigned on request by state health officers will be responsible for the medical program in

most of the rapid treatment centers now operating, and others will be assigned to those established in the future. The physicians assigned to centers are given special training in the new technics of intensive treatment of syphilis and gonorrhea at Ann Arbor and Detroit, under the supervision of Dr Udo J. Wile of the School of Medicine, University of Michigan. Public Health Service nurses assigned to the centers are similarly trained at the City Isolation Hospital St. Louis.

Every syphilis patient admitted to a rapid treatment center is given a complete medical examination to determine his physical capacity to benefit from rapid treatment and the particular method to be used. It is expected that the maximum length of stay will not exceed ten weeks. Four rapid treatment plans ranging from the one day massive dose with fever therapy to the six to eight week multiple injection method are being used at the present time in syphilis control. No one of these has been accepted as standard by the Public Health Service or by the medical profession. All of the current methods, or modifications of them, are used or considered for use at the rapid treatment centers.

Following are the rapid treatment centers by state and status of operation, as of February 13.

I Rapid Treatment Centers Already in Operation

State and City	Capacity	State and City	Capacity
Arizona Phoenix	56	Puerto Rico Aguadilla	300
Colorado Denver	40	Puerto Rico Caguas	150
Illinois Chicago	350	South Carolina Goldville	125
Indiana Indianapolis	25	South Carolina Pontiac	125
Louisiana Leesville	75	Tennessee Knoxville	50
Missouri Monett	25	Tennessee Chattanooga	150
Oklahoma Rush Springs	150	Texas Houston	60
		Utah Salt Lake City	40

II Proposed Rapid Treatment Centers for Which Applications Have Been Approved by the Federal Works Agency and the President but Which Have Not Started Operations

State and City	Capacity	State and City	Capacity
Florida Ocala	100	Panama Balboa Heights	200
Florida Wakulla	100	Tennessee Memphis	150
Louisiana New Orleans	200	Tennessee Nashville	150
Mississippi McLain	60	Virgin Islands St. Thomas	25

MISCELLANEOUS

PUBLIC HEALTH UNDER HITLER

Ergebnisse der inneren Medizin, Berlin, contains an article by Dr. Widorfer on the spread of infantile paralysis in Germany. Since 1908 epidemics of this disease have occurred at shorter and shorter intervals. While the great epidemics of 1927 and 1932 soon became extinct, the epidemic which occurred in 1938 has never been wholly subdued. Places where children are present in larger numbers for purposes of recuperation are particularly vulnerable. The average age of the patients has shifted to the older age group (many adults now become infected). It seems that the virulence of the virus and also the spread of the disease have increased. Increases in the cerebral forms of infantile paralysis have also been observed.

According to *Dagens Nyheter*, Stockholm, of Dec. 2, 1942, TT reports from Oslo. The Home Department has decreed that doctors and dentists must pay a yearly subscription of 100 kroner to be allowed to carry on their profession. The new decree is intended to strengthen the economy of the new ordered doctors' and dentists associations which have very few members.

Folkvuljan, Stockholm, of January 12, contains a front page article which states *inter alia* that during the previous session a Social-Democrat member of the Swedish Parliament, Andersson said in Rio that "one wonders at the large export of horses from Sweden." Horsepower has the advantage over manpower that sausage can be made of its producer when its strength declines, and horsepower is needed in Hitler Germany for sausage too. Just consider all the horses which have been eaten by the German divisions surrounded at Stalingrad for lack of other food. Possibly the small demand for horses in Sweden has caused the mass export of horses which is now

taking place. An advertisement by the State Export Institute of the Royal Agricultural Board in Jordbrukarnas Foreningsblad, No. 2, informs horse owners in Scania, Halland, Smaland, West Sweden and Narke that the purchase of horses intended for export will take place at forty-one different places between January 11 and January 22.

Berner Tagwacht of January 12 reports that the milk supply allowed to large cities in the south of France is catastrophic. Marseilles, Toulon and Nice receive only a few hundred liters daily, which is insufficient even for sick persons, small children and mothers. The inhabitants in these towns are receiving from the government's emergency supply 25 Gm of rice and spaghetti per head daily.

NDZ of January 4 reports an order issued by the Reich Minister of the Interior amending the order concerning the admission of doctors. The new order introduces certain relaxations of conditions for the students and thus speeds up the training. Under the old regulations the direct training consisted of six months nursing, six weeks factory or land service and six months' work as a medical assistant (*famulus*). The new order cuts down the nursing service to four months; moreover it need no longer be done before the beginning of the studies but the holidays may be used for it. The factory and land service need not in future be performed in factories or on the land but may be done in institutions and organizations which directly or indirectly work for the public health service. Finally, the order introduces certain changes in the regulations concerning examination marks. Child therapy is added to the three principal subjects of internal medicine, surgery and gynecology.

ORGANIZATION SECTION

OFFICIAL NOTES

ANNUAL CONGRESS ON INDUSTRIAL HEALTH

Fifth Annual Meeting held in Chicago Jan 11-13, 1943

DR STANLEY J SEEGER, Milwaukee, Presiding

JANUARY 11—MORNING

Report of the Council on Industrial Health

DR STANLEY J SEEGER, Milwaukee The necessity of coordinating activities of those interested in industrial health has reached a critical point. The shifting of large numbers of the population, the problems of housing and nutrition and the new hazards which are introduced by tremendous industrial expansion have all contributed to make the situation more complex. The essential medical character of industrial health problems and the necessity of medical guidance in their solution have remained a basic principle the soundness of which has become more and more apparent. The war has emphasized the fact that the American worker occupies a position which is superior to that of any other worker in the world when considered from the social, economic, medical and educational standpoints.

One of the important elements in the program of the Council on Industrial Health has been the development of cooperating agencies in the constituent state medical societies and, where practicable, in county medical societies. During the past year this activity has received vigorous stimulation from field work originating in the central office of the Council. Today the rank and file of physicians are being prepared to participate in industrial health activities to help safeguard our essential war workers.

The Council has repeatedly placed emphasis on the large number of workers whose entire medical program is provided by the general practicing physician. In smaller industries in most instances the only services in the field of industrial hygiene and health control are those which he may direct. The small plant offers numerous difficult problems when an attempt is made to supply to it modern industrial health service. The program for industry advocated by the Council stipulates the following:

- 1 A physician
- 2 A nurse
- 3 Industrial hygiene service
- 4 Proper correlation of plant health activities with those of
 - (a) The practicing medical profession
 - (b) Industrial commissions
 - (c) Units of state, county and city health department
- 5 A health program to include
 - (a) Physical examinations
 - (b) Plant inspections
 - (c) Emergency stations
 - (d) Reporting
- 6 Adequate compensation of health personnel

Definite progress can now be reported in the development of health programs of this nature. Those responsible for the conduct of industry must make industrial health programs professionally worth while. Not only must opportunities for satisfactory medical attainment be offered, but industry and the insurance carriers must take medical service, particularly in the small plant, off the bargain counter. Any one familiar with this work is impressed by the fact that many men have been discouraged not only by the professional uncertainties which surround it but by the nature of the competition which has been fostered by various agencies interested in the purely business aspects of health.

The obvious dependence of the practicing physician on the industrial hygienist and on the public health worker has been repeatedly emphasized by the Council. In order to accomplish their objectives, public health workers must make a genuine effort to foster the development of health service through the agencies of organization of the private physician. There is a growing recognition of the distinction between the functions which are appropriate to the practicing medical profession and those which belong to plant medical directors or official health administrators. The United States Public Health Service, through its division of industrial hygiene, has made most important contributions. Its states' relations have been established on a sound basis but in the light of the problem the latter activity can be regarded only as a beginning. The necessity of integrating the work of the practicing physician with that of other agencies, official and nonofficial, has not only been recognized by this council but its organization has been perfected so that such integration can be carried out effectively today. It is evident that conditions of work and their effect on health in relation to almost every human activity eventually come within the compass of medical study and research. It is hoped that industry, both large and small, can be made to see the advantage of developing health programs which will provide careers of satisfactory professional attainment so that workers may be provided with a uniformly high quality of medical service.

The Physician and Industrial Mobilization

MR CHARLES P TAYLOR, Washington D C The record of war industrial production in 1942 was accomplished by materials and men in industrial plants. The productivity and effectiveness of each man were profoundly influenced by many elements. None of these can be neglected in the future as many of them have been neglected in the past. We cannot permit conditions to continue at any point that keep us from the maximum application of manpower at the point of production. Health for the manpower is your concern but it cannot have any narrow interpretation. It means safety too and requires the intelligent integration of health and safety services from cities, states and the federal government.

There is urgent need now for health and safety education, for good food, for sound health habits for adequate recreation and for personal service and help in solving the family and home problems of the worker. Lack of ordinary sanitation in the community is an obvious danger but crowded, dirty living quarters, filthy eating places or completely inadequate ones and no decent opportunities for relaxation begin to show their effects in a hurry.

The reported figures on time lost from industry are shocking. First comes the 15 per cent of time lost by reason of accident and occupational disease. That is your specific job, and it is being well handled in most of the larger plants. The smaller plants are a different story. Then comes the 85 per cent of time lost by illness arising outside the plant. The Public Health Service and Procurement and Assignment Service are hard at work to see that medical and dental service is available even in boom towns. We need more action and less resistance from local medical societies. Now we hear of absenteeism because of other reasons, holidays, necessary shopping, need for beauty service, excess spending money, hangovers, and illness of children of mothers in the plant. We are working to eliminate the latter by setting up adequate services for these children. The other causes need organized thinking in the plant and in the community. They won't solve themselves. One manufacturer put a beauty shop in the plant and cut the absenteeism of his new women employees.

The professional leaders in this field have the great opportunity which may never be adequately recognized but which is absolutely fundamental to winning the war.

Preventive Medicine in Industry

DR JOHN H POLICER, Wilmington, Del Since in our war program few industries can avoid using chemicals, a discussion of preventive medical programs used in the chemical manufacturing industry will apply generally to all industry

The problem before us is, first, to establish a program of preventive medical control in industry and, second, to educate physicians, management and workers in the details of this program

Many physicians have entered the field of industrial medicine for the first time Among other problems they have been faced with those of industrial toxicology To a few, libraries may be easily accessible, but most new physicians in industry are being forced to learn by bitter experience The demand for information especially on industrial toxicology, has led to the planning of intensive training courses in many of our better medical schools Most such courses are too comprehensive and too detailed They do not approach the subject from the aspect of prevention but adhere to the conventional literature and procedures of industrial toxicology, giving information which helps only in diagnosis and treatment Programs which include separate sessions on lead poisoning, benzene poisoning or poisoning by chlorinated hydrocarbons are not programs to teach preventive medicine As long as they are chiefly concerned with ultimate effects of toxic agents or disease just so long are they perpetuating the old idea of diagnosis and treatment and forgetting prevention

A practical program of preventive medicine in industry must comprise two major parts first, a proper selective examination, so that workers can be allocated according to their physical ability to withstand the health hazards of the job, second properly designed and timed periodic examinations to assess the status of each worker while on the job and so to measure the efficiency of physical protective measures or to detect adverse effects of industrial or nonindustrial environment The selective examination must include all those items normally used in diagnosis—x-rays, serology, electrocardiography if necessary, as well as tests and standards which will be used in the periodic examination Too often the industrial physician is merely an examiner and does not observe his men at their work It is wrong to rely on second hand information for a knowledge of equipment and conditions in a plant Situations which may seem admirable to the most conscientious manager or safety supervisor may be seriously wrong from the medical standpoint As an example, consider the unrecognized frequency with which toxic materials are absorbed through the skin and the great practical difficulty of preventing all contacts of workers with materials which they use

The physician must know the relative degree of hazard in different plant occupations He must know it not merely in terms of the ultimate toxic action of materials handled but also in terms of tests for departure from usual physiology which are to form the basis of the periodic examination It will be useful if he knows a little of the ultimate effects of the materials used in his plant so that he will not assign a worker with a history or signs of liver disease to jobs involving exposure to compounds such as chlorinated hydrocarbons or trinitrotoluene, which injure the liver, or a man with an anemia to work with substances such as benzene, which affect the hemopoietic system If he supervises men working with new chemicals of unknown toxicity he can and should assume them to be highly toxic and not allocate to the place in which they are used any man with a history or evidence of injury to any major tissue or organ

The keystone of the program of preventive medicine is the periodic examination, which must be based on fundamental knowledge of the early effects not only of known chemicals but of chemicals which may be used in the future

Each examination necessitates absence of the worker from the job It must therefore be as brief as possible Complex procedures using elaborate equipment or technical skill are obviously ruled out So also are such manipulations as might evoke resentment from the worker or lead to possible claims of lost efficiency Studies requiring blood sampling or twenty-four hour urine specimens should therefore be reduced to a mini-

mum The need to get the greatest possible amount of information from a brief examination requires that tests used in the periodic examination must give measurements, not opinions, and the measurements must be recorded in a form amenable to statistical study

We have based a program of medical control of industrial exposure to toxic chemicals on measurements of blood pressure The method depends on first giving a score to each properly measured blood pressure according to the difference between pulse pressure and diastolic pressure and established means for these two pressure components Blood pressures at the exact mean (44 mm pulse pressure 79 mm diastolic pressure) are given a score of 10 Other pressures have scores less than 10, the score diminishing the greater the difference between the pulse pressure or diastolic pressure and the corresponding mean

Experience and statistics show that a score of 01 or less is definitely unusual and should not occur by chance alone in more than 6 per cent of a large number of normal people

The blood pressure method is but one of a number which might be used to follow development of abnormal physiologic functions It is the easiest and least expensive to apply but other methods are being investigated continually and simplified for possible general use The blood pressure method is particularly suitable for small industrial plants and therefore can fill an urgent need in the present war program

Employee-Management Cooperation for Industrial Health

MR WENDELL LUND, Washington D C Many attempts have been made to solve the problems of industrial accidents and industrial illness and malnutrition I am convinced that a major reason why we have failed so far is that our approach has in the main been one sided Because it is necessary to spend money to insure protection for workers the responsibility for industrial health and safety has rested largely on the shoulders of the employer Today the importance of war production demands that every man and woman in industry take part in the fight against accidents and sickness Organized labor frequently feels about the company safety program the way it has felt about the company union—that both are designed primarily for the benefit of management Workers feel that they have a special stake in matters of health and safety and that they should have something to say about them It is for this reason that collective bargaining contracts so often include clauses dealing with health and safety

The activities of the labor unions in the needle and garment trades are an example both of worker interest in working conditions that affect health and safety and of what can be accomplished through worker participation In this case a powerful union, determined to better the working and living standards of its members, succeeded in improving working standards as well as wages and hours in what was a notorious sweatshop industry composed of thousands of small owners weak unorganized and incapable of taking broad steps to improve conditions throughout the industry Yet the improvements brought about by the union have benefited the employers as much as the workers Employee management cooperation is now the pattern in the industry

Another large labor organization which has shown a clear understanding of the importance of health and safety measures and of labor-management cooperation in applying them is the C I O's Industrial Union of Marine and Shipbuilding Workers of America Of sixty-two collective bargaining agreements signed by that organization, forty-six contain health and safety clauses and most of these clauses provide for the establishment of joint labor-management safety committees The agreements which do not include such clauses are those signed with small subcontracting and supplier companies A majority of A F of I unions active in the shipbuilding industry have incorporated similar clauses in their collective bargaining agreements

About 1,900 joint labor-management production committees were established in war plants all over the country Three to four hundred of these have special subcommittees on safety and health

In their efforts to reduce absenteeism, these joint committees have made special efforts to attack the causes of absenteeism. For example, where colds have resulted from poor nutrition, lack of rest or personal carelessness the committee members have discussed with their fellow workers the importance of proper eating and sufficient rest, and of caution in the presence of people with colds. Where sickness or injury as a result of working conditions or carelessness has kept workers away from their jobs, the committees have attempted to discover poor plant conditions and have suggested remedial measures to management or have analyzed job methods to eliminate unsafe working habits.

In a plant making gun mounts the Production Drive Subcommittee on Health has made a study of diet and nutrition at home and at work, using literature and movies to spread the information in nutrition courses for workers' wives. This is training which shows results in the contents of the worker's lunch box and in the meal he finds waiting for him after the day's work. It is training which shows results in greater production. This subcommittee has also taken steps to arrest the incidence of oil dermatitis and to improve washroom facilities and has been instrumental in installing a shop canteen.

In a California shipyard employing many thousands of workers the joint labor-management subcommittee on safety has made recommendations and helped to put them into effect concerning (1) the use of respirators in spray painting, (2) safe construction of scaffolding, (3) improvement in sanitary conditions (4) improvement in housekeeping arrangements in the plant and (5) regulation of crane loads in shipbuilding operations. This subcommittee has also enrolled nearly a thousand men in first aid training classes and has established first aid stations at danger points in the yards.

There is a great deal of educating to be done, educating of both labor and management, before we can make any considerable inroads on the accident and sickness toll in industry. A large share of the responsibility for this education falls on the industrial doctor in his contacts with management and labor within the plant. On the management side he can make sure that the company's health and safety policies, implicit in the existence of the medical department, are understood and followed by all the supervisory employees in the plant. He can establish a close working relationship with the personnel office to help determine the job in which each new worker can achieve peak production. On the labor side he can take positive steps to know the workers and their organizations and to secure their confidence. In the matter of preplacement examinations, for example, he can make a point of discussing with the shop steward or other union officials the purpose of such examinations and the distinction between the preplacement and the preemployment examination. He should make it clear that all medical information resulting from such examinations will be held in strict confidence between the worker and the doctor and will in no way be used to the detriment of the worker but rather to insure his personal well-being and his effectiveness on the job.

One of the most constructive steps the industrial physician can take is to meet with the members of the local union in their own headquarters in order to explain to the workers themselves the purposes and principles of the plant health program and to give them a chance to ask questions and make suggestions. A series of such meetings on various subjects might be held: one on nutrition, one on venereal disease, one on control of the common cold, one on health habits, and so on. If the union has the facilities for a health program for its members and their families, the doctor might well serve as an adviser in setting up such a program.

The Labor Production Division is the agency within the War Production Board which is responsible for the best utilization of labor's energies and skills in war industry. Industrial health and safety are production problems of major importance which must be solved simultaneously with those of materials and facilities. The division staff in Washington and in the field is ready to help in developing labor participation in industrial health programs.

Procurement and Training of Professional Personnel for Industrial Health

DR CLARENCE D SELBY, Detroit. The war industries are losing doctors in considerable number. Medical service in the war industries is deemed to be essential. It cannot be dispensed with. A specialty has grown up. General practitioners are not qualified either by experience or by knowledge to take the place of the physicians who have been trained in the industries. Therefore the problem became a serious one. It finally reached the point where about 20 per cent of the physicians in the war industries had accepted commissions in the military service, and great difficulty was found in replacing them, also great difficulty in obtaining physicians to take care of expanding industries. So the matter was brought to the attention of the Committee on Industrial Health of the Procurement and Assignment Service. This committee promulgated a definition of essentiality which specified that a physician employed in a war industry, as a medical director, as a specialist, a department head or as the only physician so engaged would be essential, provided he is carrying on an industrial health maintenance program, a program designed particularly to accomplish the selective placement of women, handicapped workers and overage men in addition to the whole and healthy, and efforts based on our conceptions of preventive medicine for the reduction of absenteeism.

That original definition did not give consideration to the age of the physician. Any physician, regardless of age, who is carrying on such a program and occupied such a position in a war industry was deemed to be essential. More recently that definition has been modified to exclude physicians under 38 years of age from essentiality. In other words, any physician under 38 employed by industry, regardless of the program he is carrying on, or his status, is not regarded as being essential. However, I am informed that, in considering applicants for commissions from industry, the Procurement and Assignment Service will permit time for replacement purposes.

The Procurement and Assignment Service has instructed the chairman of the state committees to cooperate with the Committees on Industrial Health of the various state medical societies, which have been organized under the inspiration of the Council on Industrial Health in an effort to supply qualified applicants for the industries.

On request of the Procurement and Assignment Committee of the state, the Committee on Industrial Health will canvass the possibilities for qualified replacements. If none are found it will canvass further the possibility of obtaining somebody who might become qualified through a training program. That training program has been designed already and is rather rapidly being put into effect in two or three states. It does not involve a great deal of time. I will not burden you with the details, but the fact is that the Procurement and Assignment Service is quite cognizant of the needs of qualified medical service in war industries, and it has put into effect, in my opinion, an adequate program.

When the question comes before you, my suggestion is that you leave the decision to the Procurement and Assignment Board.

JANUARY 11—AFTERNOON

DR LEROY U GARDNER Saranac Lake, N. Y., Presiding

Ocular Signs of Industrial Poisoning

MR ROY S BOSSIB, New York. A large variety of industrial poisons give rise to transient disorders of the eyesight and some of them to permanent effects. Various toxic compounds may give rise to any one or more of these conditions, depending on the strength of the poison and the duration of the exposure. Other substances which formerly produced much eye trouble have been eliminated from modern processes of manufacture or the operators are better protected by the wearing of respirators and goggles, as well as the installation of exhaust fans.

Toxic amblyopia is a partial or complete blindness caused by a toxic substance which interferes with the function of the

retina, the optic nerve or the more central optic pathway. Every new drug used in medicine and every new chemical used in industry is a possible cause of toxic loss of vision so that this subject is constantly growing in scope. Victims are becoming more and more compensation conscious, and the ophthalmologist, in order to be fair to both employer and employee, must have a thorough understanding of this subject. Persons who have been exposed to poisons which affect the optic nerve or the retina as a rule complain of temporarily disturbed vision as a first symptom. Recently acquired color blindness is an early symptom of poisoning. Another common symptom is disturbed vision described as heat waves. Diminished sharpness of vision and general depression of the visual fields bring the victim to an ophthalmologist usually with a request for glasses. The characteristic changes in the fields are a central blind or partially blind area in the visual field and disturbances in the color field. There may be deficiencies in accommodation. Carroll divides toxic amblyopias into three groups: (1) those caused by poisons which produce cortical or central blindness, (2) those caused by poisons depressing the entire visual field, but more especially the peripheral fields, and (3) those caused by poisons depressing exclusively or chiefly the central visual field.

Many volatile substances may seriously affect vision. Any substance that will cause accumulation of a fluid in the brain will cause a similar response in the eye.

Occupational keratitis as well as several other forms of keratitis are treated by Fuchs under diseases of the conjunctiva, and occupational conjunctivitis is defined as "an acute conjunctivitis found in certain industries where irritants—acid vapors, liquids or dustlike particles—get into the eyes either by accident or as part of the day's work."

Davidson asserts that true occupational dystrophy such as is reported in textbooks and in the literature has not been observed. It should be the axiom in safety practice that there is no such thing as a minor hazard to the eye.

It is the responsibility of every safety engineer, of every physician or surgeon having any industrial practice and of every industrial nurse to become familiar with all the poisonous substances used in their respective plants and to take all possible steps to protect the employees who are exposed to these poisons.

Newer Concepts in the Prevention and Treatment of Wound Infections

DR. AUSTIN E. SMITH, Chicago. Various attempts have been made to define the properties of a good disinfectant for local use, but the prerequisites of a chemical agent remain, essentially, high activity against infecting organisms, fast action, low toxicity for human tissue, efficiency in the presence of organic matter, ability to penetrate tissue, solubility, stability, absence of unpleasant odor, absence of deleterious effect on instruments and comparatively low cost. No one agent has yet met all these requirements, although many preparations have been of inestimable value as aids in the prevention and control of infection. Certain agencies have taken steps to cope with the situation. The Food and Drug Administration now demands not only adequate labeling but definite antibacterial activity for new agents. The Council on Pharmacy and Chemistry, in recently adopting criteria for surface antibacterial agents, proposed that certain prescribed data be submitted when a manufacturer presents a preparation for Council consideration.

Under the laboratory section of the American Public Health Association there has been set up the Standard Methods Committee for the Examination of Germicides and Antibacterial Agents. At present this committee has referees for antibiotic agents, chemical antiseptics, chemical disinfectants, detergents, fungicidal and fungistatic agents, disinfection of air by germicidal vapors and mists and disinfection of air by ultraviolet irradiation.

Clinical knowledge has changed and is changing daily the practice of anti-infective therapy. The sulfonamides are one of the best examples for the cause of such changes. Effort to lessen the confusion over the number of agents in use by determining their specific values and by minimizing this number has made some progress.

The sulfonamides have created striking changes in the handling of wounds and the treatment of infection. Sulfanilamide, sulfathiazole and sulfadiazine locally have produced, as compared to the results of wound therapy of a few years ago, almost miraculous cures. Locally the sulfonamides have been applied as powder and in ointments, emulsions and solutions. It is interesting to note, however, that certain leading scientific bodies have declared that the local use of such preparations requires much more investigation.

Ultraviolet radiation has been advocated for sterilizing the air of operating rooms to prevent wound infection during operations, for use in wards of infectious diseases to prevent cross infection, for the sterilization of footwear, drugs, instruments, water and many other things. Notwithstanding the many unknown factors in this problem, the use of ultraviolet lamps for the control of infections which may be due to contaminating organisms from the surrounding area merits further investigation for application in hospital units, plants and laboratories. An example of industrial application is the use of ultraviolet germicidal ray lamps by some manufacturers of pharmaceuticals to keep the air as nearly sterile as possible in the vicinity of operations calling for the filling of ampules.

The spraying of chemical agents into the air to render that air sterile is not new. Recently this procedure has been subjected to renewed investigation and interest, and a number of agents, including propylene glycol, are being studied. While much of the work in this field has been of an experimental nature on the control of influenza infection, some work has been done on streptococci, staphylococci, pneumococci, *Hemophilus pertussis* and other organisms. Some contradictory findings on the control of air borne beta-streptococci have been found to be due, at least in part, to changes in the humidity, high humidity apparently neutralizing the germicidal action of the propylene glycol vapor employed. Present work suggests that the amounts that have been necessary in the past for experimentation are not toxic. The pure vapor appears to be more effective than the so called aerosol.

Detergents, both anionic and cationic, have received some investigation and again some recognition as antibacterial agents or as adjuncts to other anti-infective compounds.

Some ingredients of soap are claimed to have anti-infective properties. The Council on Pharmacy and Chemistry has periodically been requested to consider certain of these preparations and has found in each case that the claims exceeded the possible therapeutic effects.

Quaternary ammonium compounds have been suggested as anti-infective agents. This group of compounds is receiving much attention and appears to offer considerable promise for certain uses.

There is a class of agents that is currently the object of considerable attention because of the effectiveness of its members against certain bacteria of which they are extracts. This group of compounds has variously been called "metabolites" and "antibiotics" and includes extracts of fungi and bacteria. The following representative examples have been demonstrated and purified to varying degrees: gramicidin, tyrocidin, actinomycin, citrinin, penicillic acid, streptothricin, gliotoxin, proactinomycin, tyrothricin, penicillin, fumigacin and clavacin. All are being studied for specificity, comparative effect with other bacterial agents such as sulfonamides, the most effective mode of application and optimal dilutions, but isolation and identification remains to be achieved. Members of this group are almost specific in the treatment of certain infections, the most striking effects having been observed following application to gram positive and certain gram-negative bacteria. In many instances the action is bacteriostatic, in other instances, definite bactericidal action may be elicited. Regardless of the ultimate findings attention may well be directed to these agents in the hope that valuable aids may be added to the medical armamentarium.

While investigations on specific agents are proceeding at headlong pace, the prevention and treatment of certain types of infection also are receiving due attention. Thus some practices in therapeutics are being approached from two sides. For example, fungous infections such as ringworm are in a sense wound infec-

tions. Since they are the source of much trouble in industry as well as elsewhere, innumerable new agents and variations of old treatments are being tried. These measures range from the direct application of organic and inorganic preparations to the feet, stockings and shoes to the ultraviolet irradiation of foot-wear. However, the ideal agent or method has not been demonstrated. At present the Council on Pharmacy and Chemistry is undertaking a survey of agents used in this field in an effort to establish criteria for the evaluation of drugs used in the prophylaxis and treatment of fungous infections, to determine their merit on a comparative basis and to define the allowable claims which may be made for their effectiveness.

Recognition, Prevention and Essential Treatment of Occupational Dermatitis, with Particular Reference to Oil Dermatitis and Folliculitis

A full report by the Committee on Occupational Dermatoses, American Medical Association, Dr. Harry Foerster, chairman, will appear in *THE JOURNAL* at a later date.

Respiratory Infections in Industry

This joint report, by the Council on Pharmacy and Chemistry and the Council on Industrial Health, presented by Dr. Chester S. Keefer, appears in full in this issue, page 802.

Program of Immunization for Industrial Workers

1. Vaccines and Serums: Indications and Procedure

DR. JAMES P. LEAKE, Bethesda, Md. Though the risk from smallpox has decreased definitely in the United States as the result chiefly of the ordinary electric refrigerator with its freezing compartment where smallpox vaccine can be kept, the danger from fatal smallpox has not been extinguished, as last year's outbreak in Glasgow, Scotland, reminds us.

Our position on the immunization against smallpox may be indicated as follows:

1. Vaccination is the most important measure in the prevention of smallpox.

2. There are limitations to the value of vaccination in preventing smallpox, especially in regard to the duration of protection.

3. There are disadvantages, not always appreciated, in vaccination, especially if due care is not given to the procedure.

4. The hazards of smallpox have been diminishing recently, and before any given program of vaccination is adopted the advantages should be weighed against the disadvantages with respect to the various conditions in the employment concerned.

5. Thorough preemployment or early postemployment vaccination, if applicable, is the most desirable form of protection for industry and should be required in some places where the population is shifting. Active tetanus immunization with toxoid is used in the Army and Navy and is good. The Army has been using the fluid toxoid, the Navy the alum precipitate. In using alum precipitate it is worth while to put the needle parallel with the humerus, and not across, so that the injection is as deeply subcutaneous as possible, not intramuscular but so the deposit of the material isn't just under the skin. It remains there and sometimes becomes fluctuant. If some physician who doesn't understand those things sees it, it may be incised. It shouldn't be incised. They are not abscessed. They will go away, in general, with practically no attention at all.

Program of Immunization for Industrial Workers

2. Problems of Organization and Administration

DR. WARREN F. DRAPER, Washington, D. C., Presiding

Industrial Physical Examinations

This report by the Committee on Physical Examinations of the Council on Industrial Health, American Medical Association, Dr. Harvey Bartle, chairman, will appear in full in *THE JOURNAL*.

The Toxicity of Military Explosives

DR. LEMUEL C. MCGEE, Wilmington, Del. Explosives are chemical compounds which can be made to break down rapidly and release energy through the formation of comparatively large volumes of gas. The various military explosives are prepared by simple chemical reactions and possess well known chemical and physical properties. Propellants such as smokeless powder liberate their expanding gas energy mass at a lower velocity than do high explosives, of which trinitrotoluene is an example. Some chemicals which are required in, and some compounds which arise out of, the manufacture of military powders and explosives have a toxic action on human tissues. This discussion concerns medical experience with a few of these substances.

Moderate exposure of man to toluene for a few hours results in fatigue, drowsiness, headache and evidence of depression of the central nervous system. If continued, such exposure causes muscular weakness and incoordination, nervousness, paresthesias and confusion. Acute poisoning by toluene can result in convulsions and death through respiratory paralysis.

Trinitrotoluene, (TNT, trotyl, trinitol, tolite, triton or trilit) may enter the body by absorption through the skin, by inhalation of dust and fumes or by ingestion along with food and drink. It colors the skin yellow. Many such stained workmen have no complaints, others have skin irritation. When a mild dermatitis appears during the first few days or few weeks of exposure it is prone to clear spontaneously even though the workman continues his contact with trinitrotoluene. When the dermatitis appears in a worker having had several months to a year or more of contact with trinitrotoluene the lesions are apt to persist until the worker is removed from contact. Trinitrotoluene can damage the liver. Physicians who follow the experiences of trinitrotoluene workers feel that some persons are particularly susceptible to toxic effects of the compounds.

The most common complaint of workers in dinitrotoluene is that of an unpleasant, metallic, bitter taste in the mouth. Other symptoms are muscular weakness, headache, loss of appetite, vertigo, nausea, vomiting, insomnia and pain, numbness or tingling sensations in the extremities. The chief findings from clinical examination of intoxicated dinitrotoluene workers are pallor, cyanosis and anemia.

Tetryl (trinitrophenylmethyl nitramine) is used as a filling for detonators and as a primer for high explosive shells. Because of its finely divided physical state tetryl dust readily floats into the air. Coryza with sneezing, lacrimation and blepharitis with sticking together of the eyelids are common. The commonest complaint from tetryl workers is that of dermatitis. Lesions of the skin and bleeding from the nose are early manifestations of tetryl irritation. Symptoms which appeared late, usually after exposure of several months, are ease of fatigue, headache and loss of weight.

Fulminate of mercury ($\text{Hg}[\text{CNO}]_2$) is highly irritating to the human skin. Experienced workers on getting fulminate sores have learned that it is worth while to use a magnifying glass to enable them to find and remove crystals of the compound which lie buried in the lesions. Prolonged exposure to fulminate occasionally results in systemic mercurial poisoning.

The toxicology of the oxides of nitrogen has received extensive investigation. The clinical picture of nitrous fume poisoning may be one of several types. The most constant effects are those which refer to the respiratory tract. Poisoning by nitrous fumes usually leads to some degree of edema of the lung. The treachery of nitrogen dioxide lies in the seeming mildness of damage to the exposed man initially. The effects of exposure are notably insidious.

Diphenylamine, also known as hexite, is a derivative of aniline and is used extensively as a stabilizer in explosives containing nitro compounds. In American industry no instances of poisoning from exposure to this compound have been reported in recent years.

Lead azide (PbN_6) is an initiating compound used for bringing about detonation of high explosives. In spite of the potential hazard of lead poisoning, I have found no published reports of its occurrence in American plants preparing or handling lead azide.

Optimum Hours of Work

DR JAMES G TOWNSEND, Bethesda, Md There is a point where one can labor to maximum production and keep within a minimum number of hours There are many variables, the type of work, its intensity and the type of employee, to consider Older men, women and younger persons show signs of fatigue more readily than the young, while individual who has been on the job a longer time and is used to it Myers, in his work on industrial psychology, emphasizes the fact that every reduction in the working day leads to a decrease in accidents, spoilage of work, sickness and absenteeism The reduction of working hours from twelve to ten, he says, leads to an increase in hourly and daily output The reduction of working hours from ten to eight leads to a further increase in daily and hourly output, except in operations whose speed depends mainly on the speed of the machine The reduction of working hours below eight, although increasing hourly output, does not usually lead to an increase in daily output

Collier, in his work on outlines of industrial medical practice, says that a categorical answer to the question "What is the optimum hours of work?" is difficult Evidence accumulated over a long number of years and in various occupations shows that, if hours of work habitually, or for long periods of time, exceed forty-eight per six day week, industrial health and efficiency are bound to suffer

Brown of Princeton obtained opinions from executives of 128 companies Sixty-nine executives of the 128 circularized preferred a forty-eight hour week Brown states that the opinion seems to be unanimous that hours less than forty a week do not increase individual productivity, and hours above sixty a week decrease productivity and increase absence and accidents

An advisory committee of government officials, together with industrial labor, has just met at the Department of Labor to secure a policy on optimum hours, concurred in by the War and Navy departments, the War Production Board, the Maritime Commission and the Departments of Labor and Commerce and Public Health Service A joint committee examined all the available evidence, including studies made by experts and the practical experience of management and labor The recommendations of this committee are pretty general and make ample allowance for temporary emergencies when, for a short time, longer hours or seven day weeks may have to be worked out Furthermore, allowance is made for some variation in the optimum work week on different types of employment In order for a plant to make this evaluation it is recommended that daily and weekly hours of employees in war production plants should be reexamined to assure those schedules which will maintain maximum output over a long war period Hours now worked in some plants are in excess of those which can be sustained without impairing the health and efficiency of workers and reducing the full production Plants which are now employing individual workers longer than forty-eight hours a week should carefully analyze their present situation with respect to output and time lost because of absenteeism, accident, illness and fatigue It is also recommended that one day a week should be devoted to rest, with a thirty minute lunch period and a vacation Vacations should be staggered and spread over the longest possible period Vacations should not be permitted to excuse any shutdown of any department of any war production plant, except where such shutdown would not curtail production

In order to assist plants to analyze their work week, a check list was prepared The War Production Board has sent the list to over fifteen hundred labor-management committees, and it has been reprinted in many of the labor journals It was realized when this check list was sent out that a good deal of confusion had been created by the emphasis given to the statistics on average hours released by the Bureau of Labor Statistics These averages concealed the fact that many plants had been working hours that are much longer than the average, and it is precisely to this group that the hours recommendation is addressed

This check list we do not have for distribution, but it is about the same size as the pamphlet containing the recommendations on optimum hours It says on the face of it "This is not a government questionnaire It is for your use in the plant

and it is not to be returned to any government agency" The check list calls attention to how to locate what we call trouble spots "Have you had an increase in accidents? Have you had an increase in absenteeism? Have you had an increase in labor turnover? Have you had a drop in output per worker or increase in spoilage, and rejects or poor quality of work? Have you had an increase in grievances or disciplinary cases for no apparent reason? In what departments or working units are any of these symptoms found? What hours per week are in effect in the departments or units in which these troubles, symptoms appear?

"The most efficient hours schedule for sustained maximum production depends, in part, on the type of work, the best hours to be determined by keeping certain records for each department or for operating units within departments"

Then the check list tells how the records should be kept, a record on output, which is the number of units produced per man-hour, man-hours per unit of output, the number of units rejected per man-hour, the time lost because of accident, illness voluntary absenteeism It is explained how to keep such a record To measure, for example, the time not worked by persons who were scheduled to work If 100 workers are scheduled to work 48 hours a week, that is 4,800 hours If 20 are absent, 1 a day for an 8 hour day, that is 160 hours per week, 160 divided by 48 is 33 per cent absenteeism

Then plants are asked to keep records of the accident frequency rate and the number quitting because of too long hours, the number of grievances arising out of too long hours, and a comparison of absentee records with earlier periods Ways to determine the best daily and weekly hours and sample forms of tables are shown It is some gratification to know that this pamphlet, through the combined thinking and action of eight different government agencies, has been responsible for being of some help in pointing toward solving a perplexing problem

Women in Industry

The preliminary report of the Committee on Health of Women in Industry, Section on Obstetrics and Gynecology, American Medical Association, Dr H Close Hesselstine, chairman, appears in full in this issue, page 799

Prehabilitation A Report and Recommendations

DR WILLIAM A SAWYER, Rochester, N Y A health project for industrial trainees was set up in Rochester, N Y, about two and a half years ago The total cost of this prehabilitation project over a two and a half year period (up to Dec 31, 1942) has been \$18,087

The trainee in the Rochester project is given a complete pre-placement medical examination, of the type given at larger industrial plants of the city, at the time he registers for a shop school course His physical condition and defects are noted on a special record card with a separate blank for past medical history In addition to the general check-up, the examination included a urine examination (discontinued in February 1942 because of a lack of personnel, but to be resumed shortly), a tuberculin skin test and a Wassermann test All persons who react positively to the tuberculin skin test are urged to have an x-ray examination of the chest at the County Sanatorium All but 9 per cent have availed themselves of this opportunity Those who have not are periodically (every two months) sent a letter urging them to make an appointment for an x-ray examination

Following the medical examination, a preliminary rating is made At the time of being notified of the rating the trainee is urged to visit the Tuberculosis and Health Association office There the record is reviewed and the noted defects are rechecked with the objective of qualifying the trainee as soon as possible for employment "specifically cited" Arrangements for necessary treatment are made through personal physicians or existing community facilities, as under no circumstances does the medical consultant give treatment or do nurses make home visits for treatment purposes Clinics and hospitals as well as private physicians, are most cooperative in this respect The medical consultant suggests the type of work the trainee is capable of doing Fitting the man for the job he is physically qualified to fill is the most significant feature of the project

All trainees found to have definite visual and hearing defects, cardiovascular disease, diabetes, kidney disease and other chronic diseases were referred to clinics or private physicians, and physicians were requested to give reports of present status to the employment service. In the original ratings hernia (138 cases) was an invariable cause for rejection and therefore 45 trainees were referred for surgical treatment. Of the 210 trainees (4 per cent of the total examined) found to have varicose veins, all except 4 were approved for some form of employment after reexamination. The 65 (1.24 per cent) trainees having positive Wassermann reactions, having satisfied health department authorities that they would continue under treatment, were subsequently approved for employment with one exception. Arrangements were made to give smallpox vaccinations to men with no vaccination scar.

Defects Noted

Total industrial trainees examined	5 242 (1 534 women)	
Underweight		567
Overweight		1 203
Vision distant pronounced		541
Slight		696
Near pronounced		538
Slight		417
No vision in one eye		121
Teeth Caries		1 116
Pyorrhea		57
Cleaning		251
Extraction		132
No teeth		8
Infected gums		50
Low hemoglobin	Pronounced	57
Slight		100
Tonsils	2	155
	3	100
	4	49
Infected		12
Thyroid		117
Hearing	Pronounced	84
Slight		93
Heart murmur		223
Rapid pulse		12
High blood pressure		549
Low blood pressure		97
Hernia		138
Relaxed rings		86
Skin condition		59
No vaccination		151
Scoliosis		32
Varicose veins		210
Relaxed arches (flat feet)		433
Varicocele		96
Hydrocele		15
Genitourinary		18
Gonorrhea		3
Positive tuberculin skin test		1 726
Positive chest x-ray examination		40
Positive Wassermann reaction		65

Of the total examined, 1,726 (33 per cent) were found to have positive tuberculin skin tests and were referred to the County Tuberculosis Dispensary for chest x-ray examinations. Of this number 4 by 5 photoroentgenograms were taken of 1,567 (91 per cent). A total of 40 cases of clinically significant tuberculosis (0.76 per cent) were discovered after 150 (9 per cent) were given repeated x-ray examinations at the sanatorium. Of the 1,059 trainees seen by the medical consultant, 951 were found to be employable, 242 in selected jobs.

In this prehabilitation program, effort was concentrated on the correction of the following defects or conditions: Overweight, 1,203 by treatment. High and low blood pressure, heart murmurs, 646 by reference to work specifically cited. Pronounced near vision, 538 by examination for glasses. Pronounced distant vision, 541 by examination for glasses. No vision in one eye, 121, special job assignment being recommended. Hernia, 138, of whom 45 were referred for surgical treatment others by wearing a truss. Pronounced hearing defects, 84, with special job assignments. Positive Wassermann reactions (syphilis) 65, by physician treatment till Wassermann reaction becomes negative. Tonsils grossly enlarged and infected 61, by operation or treatment. Anemia, 57, by treatment. Positive sugar or albumin in urine, diabetes, 54, by physician or hospital treatment till urinalysis was negative. Infected mouth conditions, 50, by dental treatment. Tuberculosis, 40, by medical supervision through county sanatorium. Gonorrhea, 18, by physician treatment till culture was negative.

A total of sixty-seven physicians have participated in the physical examinations. Approximately six are examining at any one time. They are assisted by two nurses (full time) and eight nurses (part time, during clinic sessions only). Physicians are paid \$1 for each examination, and clinic nurses are paid at the rate of \$1 an hour. The medical consultant received a small monthly honorarium. Clerical service was in charge of a trained information secretary. She was given office assistance. Every six months home visits are made to those who have not responded to letter follow-up. Through the two and a half year period of the operation of the project a number of improvements in procedure and changes have taken place.

Among the procedures recently carried out which have improved clinic service have been the centralizing of activities in a central clinic, holding two sessions a week, the central housing and handling of all records and an increase in clinic service provided, which has made possible the speeding up of rating and referring to cooperating agencies.

Recommendations 1. A community replacement medical examination consultation, refer service is essential, especially in wartime, when there is a manpower shortage. It can be carried on at a reasonable unit cost if the various agencies interested help to bear a part of it. With all items included, the cost will not be less than \$5 per person examined.

2. Examination should be compulsory. Those found not to be employable should be eliminated from shop school instruction. The seeking of medical advice regarding job placement should be made compulsory.

3. It is believed that there should be some way of requiring trainees to have defects corrected before completing the course.

4. No financial provision need be made for corrective care but some provision should be made for recording the care sought and obtained.

5. At the time the trainee is recommended for employment there should be a certification that those recommended for job placement are free from active tuberculosis, infectious syphilis and any other communicable diseases or conditions dangerous to fellow employees.

6. During the course of training advice regarding the importance of good health habits and nutritional needs should be systematically presented in their relationship to efficient work capacity. Health education is a vital part of prehabilitation.

The Older Worker

DR. ANTON J. CARLSON, Chicago. This article appears in full in this issue, page 806.

JANUARY 12—MORNING

DR. RAYMOND HUSSEY, Baltimore, Presiding

SYMPOSIUM ON MEDICAL RELATIONS IN WORKMEN'S COMPENSATION

Report of the Committee

DR. RAYMOND HUSSEY, Baltimore. The Committee on Workmen's Compensation of the Council on Industrial Health has been in existence now for eighteen months. Our effort has been one of achieving orientation in this field. Workmen's compensation is complex and heterogeneous. Many of us are inclined either not to think at all about workmen's compensation or we are inclined to think of it rather lightly.

There is a great deal of adverse criticism by the representatives of the various agencies concerned with the development and operation of workmen's compensation. That is particularly true in the papers that are read at the meetings of the International Association of Accident Boards and Commissions. I have been impressed with the almost venom one encounters in reading the proceedings of that organization, and it is usually aimed either at the insurance group or at the medical group.

If we stop and think of what the situation in medicine and in law and insurance was when workmen's compensation was first started, we shall find much to feel encouraged about. In 1911 when the first workmen's compensation act became effective—that was in Wisconsin or California if I remember correctly—medicine was largely a neighborhood practice. The attitude of

the medical man toward his patient was extremely private in nature, what we usually speak of as the physician-patient relationship. He regarded whatever he learned about the patient in great confidence and kept that information in confidence.

The legal profession had been buried for years in the idea that damage claims for personal injuries were carried on through action of what the lawyers called "tort," which has to do with the fault or negligence of some one else, and with respect to industrial injuries they had the master-servant concept in the law. An interesting paper was written by Mr. Tom Bartlett of Baltimore in which he leaves me with the impression that for lawyers to be separated from that idea of the master-servant concept is pretty much the same as taking away our idea of the Holy Trinity. Administrative law, in which workmen's compensation is included, was hardly popular to say the least. Lawyers distrusted this type of law.

Workmen's compensation is more than merely a provision for benefits and the payment of the cost of medical care. Too frequently one's idea of workmen's compensation stops with that concept. Equally important is prevention of accidents or disease, and the rehabilitation of the injured person. I feel that that triad must be regarded as the fundamental principle of workmen's compensation.

What was the status of medicine at the time workmen's compensation commenced? Public health was in its swaddling clothes. We had no one, so far as I am aware, in this country who was appointed health commissioner. We had no public health schools. We had practically no instruction in public health. Preventive medicine had hardly commenced to breathe. Administrative medicine was in the blastodermic stage.

There are two things that we ought to attempt to accomplish. One is to hold meetings between the various groups interested in workmen's compensation where points of view can be expressed, where corrections can be made in points of view and where we shall have a basis for common understanding.

All of us must recognize that we do have a new branch of medicine, administrative medicine, which deserves a much more prominent role in the commissions that administer compensation laws. In my opinion all hearings on disputed medical issues should be before medical men. One of the greatest difficulties that has been emphasized all through this work has been the absurdity of medical testimony and the ridiculous judicial decisions that are made from time to time. We must keep in mind always, it is true, that workmen's compensation is social legislation. It is a legal system but it is also a social system, and the judiciary certainly are influenced in their liberal interpretations because of that.

We have had enough information accumulated in Maryland with the Medical Board for Occupational Diseases to indicate that the testimony that physicians give when the hearing is before medical men is entirely different from the testimony they give when it is being heard before laymen. All laymen like to dabble in medicine, but when they have no background in physiology, pathology or biology it is merely having so many words in one's mind. Sometimes the way they are employed is rather funny so far as the medical man is concerned.

One of the problems of workmen's compensation that is crying for help is the problem of disability determination. It is one thing to say that and it is quite another thing to do something about it. It is an extremely complex field of effort. I hope sometime within the next year it will be possible for us to get a group interested in doing something that has never been done, and that is to state clearly what the problem of disability determination really is.

The most frequent criticism made of medicine in workmen's compensation is that it is not an exact science. What is an exact science? The term "exact" is relative. Physics was regarded as an exact science until radioactivity was discovered.

The American Medical Association, through its Council on Industrial Health, is intensely interested in doing something in the field of medical relations to workmen's compensation, and we cannot do it unless we get the cooperation of all parties concerned.

I hope that we may regard this as the first annual conference on this subject.

DISCUSSION

MR. J. W. HOLLOWAY JR., Chicago. The Bureau of Legal Medicine is happy to collaborate with the Council on Industrial Health in initiating a conference of this type. Our contact with the problem of workmen's compensation is limited to a study of pending legislation or proposed legislation in the different states. We have a legislative reporting service that sends us copies of all legislation of any particular interest to the question of public health or to physicians. We get copies of all state legislation on workmen's compensation, and as far as we are able to do so we study those proposals and abstract them and publish them in *THE JOURNAL*. Our other contact with the problem is through court decisions. We try to keep in touch with the current decisions of the courts of record, the courts whose decisions are published, and compile these cases, and we are trying to develop in the Bureau a fund of information to which the various state medical associations, the county medical societies and physicians may turn in case they need information of this particular type. We are constantly receiving inquiries from physicians all over the country who have been called to testify in workmen's compensation cases, asking for information that will qualify them really to testify as experts. The information may be available, but unfortunately it is not very accessible at the present time.

Allergy Its Place in Compensation Procedure

DR. J. A. CLARKE JR., Philadelphia. This report may be useful to legislators and compensation boards of various states in their efforts to dispense justice.

I. Allergy is a term used to explain certain diseases of man resulting from contact with various substances foreign to the individual. It differs from the usual diseases in that in allergy a special abnormality exists in the affected individual rather than in any harmful quality inherent in the substance which produces the disease, which appears then through no fault or neglect of either the employer or the employee. It is therefore purely accidental (dependent in some measure on a constitutional defect in the individual in which inheritance plays some part) and little if anything can be done to prevent it.

Allergy may be defined as an unusual reaction on second or subsequent exposure to substances that are ordinarily considered harmless. An excessive response to natural irritants is therefore not an allergy, as some observers claim, and such quantitative variations appearing particularly in the skin are not considered in this report. (Idiosyncrasy more accurately describes such conditions.)

The foreign substances causing the allergic symptoms are known as allergens, and the person in whom the symptoms appear is known as an allergic person. The allergic diseases recognized at the present time are asthma, hay fever, certain cases of nasal congestion, certain dermatoses (eczema) and urticaria. Any one or all of these diseases may be produced by allergens encountered in industry, but the symptoms may not appear until after months or years of contact without symptoms.

If any employee eligible for compensation becomes incapacitated because of an allergic disease he should be studied by a physician skilled in allergic methods. The result of the study should be made the basis of any settlement.

II. After such a study, the majority of the sufferers will fall into one of the following classifications, which it is hoped will be accepted and used as the basis of laws and rulings.

A. When the allergic person becomes sensitive to an allergen which he encounters only in the pursuit of his occupation, thus making it impossible for him to pursue this occupation. Allergic treatment cannot be relied on because contact with the allergen in industry is usually excessively great. The injections decrease a person's sensitivity and he is correspondingly relieved of his symptoms. However, since this relief is only relative, the result is not likely to be satisfactory. It should be attempted only under unusual circumstances, in which case the possibility of failure should be realized by both the employer and the employee. Such persons should receive compensation in the form of weekly payments for a fixed and limited period sufficient to enable them to secure other employment.

Note 1 While a person is becoming sensitive to a substance in his occupation, he is likely to become sensitive to other substances, particularly in his home. Discovery of any other substances to which the sufferer may be sensitive should not influence the case in any way.

Note 2 It is impossible to determine how long a time interval is necessary to develop a sensitivity. Therefore when a man is employed in the same occupation by a number of different employers the firm employing him at the time the allergy appears should be arbitrarily liable for compensation.

B When the allergic person becomes sensitive to an allergen encountered in large quantities in his occupation but encountered in less quantities outside. Here the damage is greater than in A because symptoms will persist for years after he finds other employment.

It is at least reasonable to presume that the excessive exposure in his occupation largely contributed to his sensitivity. Under these circumstances an attempt at allergic treatment is imperative and the cost of this treatment should be added to the compensation allowed in A. The limits of such compensation should be fixed arbitrarily.

C When an allergic person becomes sensitive to an allergen largely encountered outside his occupation but present also at his work. The employer alone cannot be held accountable for this illness. On the other hand the worker will be unable to pursue his usual occupation in the future.

In this group the occupation is at most only a contributory cause of the allergy. The man would have become allergic in any employment but is unable to pursue his present job.

In this group justice is not as simple as it is in A and B. Since the employment is only a minor cause of the disease the employer should not be held responsible for future treatment. However since the nature of the employment precludes the possibility of the employee continuing at his old job it would seem just that he receive a limited compensation to pay for his loss of time while seeking other employment.

Note Many persons in this group can be given other work by the same employer in which he will not be exposed to the allergen to which he is sensitive. If this is possible it should relieve the employer entirely of further responsibility.

D When an allergic person becomes sensitive to substances never encountered in his occupation. It would be unfair to hold the employer responsible in any way for this illness unless contributory factors in E or F can be shown.

In the present state of our knowledge of allergy it is comparatively easy for a trained allergist to prove beyond doubt the sensitivity of a person to substances found in his occupation. Unless proof of contact while at work with an allergen to which the allergic person is sensitive can be furnished the employer should not be held.

E In respiratory allergy there can be little doubt that acute infections, from simple colds to pneumonia may greatly aggravate allergy from any cause. Compensation under this heading should be allowed only when the following conditions are satisfied:

1 Unusual exposure in line of duty while employed must have occurred.

2 Evidence of an acute infection within a few days of the exposure must be presented.

3 The allergic conditions must appear or be aggravated within a few weeks of the acute infection.

These requirements must be rigidly enforced. Furthermore the maximum compensation under this group should be set arbitrarily. The acute infection should not be regarded as the cause of allergy but only as an aggravant. The employer's responsibility should therefore be limited.

Such compensation should include payment of loss of time from work and payment for treatment. Since infectious allergy may be very chronic definite limits of liability should be set.

F It was formerly believed that nervous factors, such as fright, accidents or undue tension were important in the etiology of many allergic conditions. It is the opinion of the majority of this society that this view is no longer tenable and should not be considered in workmen's compensation. To avoid further confusion it would be well to exclude by a statute or ruling,

nervous factors as either a cause of or an influence on allergic conditions, and if allowed, to define its limits rigidly and to decide—

1 Whether accidents while employed should be considered as a cause of allergy.

2 If so what maximum interval should be allowed between the accident and the onset of the allergy.

3 Whether unusual nervous tension during ordinary employment should be considered a cause of allergy.

If allowed by law, compensation should include payment for the time lost and payment for medical treatment, the limits of which should be arbitrarily set.

All of those in groups A and B suffer from unfortunate, unpredictable and unpreventable illness due to employment. As such they come well within the spirit of workmen's compensation. Likewise rigidly selected persons under classes C, E and F have had their suffering increased as a direct result of their employment and are entitled to appropriate compensation.

On the other hand, those in class D can show no connection between their illness and their employment and are not entitled to any compensation.

The majority of allergic sufferers belong in class D. The just and equitable claims of the small percentage in the other groups would be a very slight burden on industry. Laws and rules should be designed to exclude persons in class D otherwise employers will be prejudiced against employing allergic persons. A well trained allergist should have no trouble in determining into which of the six groups an individual belongs.

DISCUSSION

DR NATHAN B. HERMAN, Baltimore. It was stated in this report that 'Likewise rigidly selected persons have had their suffering increased as a direct result of their employment and are entitled to appropriate compensation. Unfortunately, compensation does not deal with suffering. Compensation deals with loss of time with incapacitation. That alone would indicate that the framers of this report have not had much actual experience with the administration of compensation acts. The report medically is an excellent one, but administratively it poses so many difficulties that I do not believe it would be of a great deal of help to compensation boards. After defining allergy the report says 'It is therefore purely accidental. As soon as you introduce the word 'accident' you get into great difficulties, indeed in the administration. Under degree of exposure the report says that material may be encountered largely in occupation or largely out of occupation. Lawyers will argue endlessly and medical boards particularly about this administrative pitfall. The paragraph dealing with respiratory allergy also presents great difficulties and I doubt if it is feasible to follow the outline. Lastly a great deal of the responsibility devolves on adequately trained allergists. We have endless discussions and it is not easy to determine so specifically the sharp demarcations indicated by the report. We owe a real debt to the committee for bringing in the report. It is helpful and presents a skeleton on which we can group further ideas.

MR THOMAS N. BARTLETT, Baltimore. The report gives a great deal of food for thought. Lawyers and claims men must deal with these cases from an insurance standpoint. Some schedule could be worked out in these cases to pay a certain compensation for a certain period of time by the employer under whom the man first manifests the allergic condition and disability. After the man gets over an attack he may not go back to work for the same employer. Even if he does go back to work for the same employer how far can you go in awarding compensation for a succession of periodic disablements? A man may be allergic to one thing or he may be allergic to half a dozen things all of which are contributing factors, some relating to his employment and some not. I think the report is a start toward some definite information and as a basis for some definite plan in compensable cases. From the medical point of view the problem is a big one from the preventive aspect.

MR BENJAMIN MARCUS, Detroit. I am associate counsel of the U. A. W.-C. I. O. and I am interested in the problem of drafting workmen's compensation acts. The suggestions contained in this paper present certain serious problems about

drafting of workmen's compensation acts. If we treat every disease in a separate chapter we are going to have a law so unwieldy that it is going to be difficult, if not impossible, to administer. Two problems are raised. First, the question of limitation of liability in regard to allergic diseases. From the employee's point of view we are opposed to any special limitation on liability in relation to a specific disease. We believe that liability should be determined by the legislature in relation to all disabilities and that liability should govern no matter what the cause, whether it is allergy or dust disease or accident or anything else. The other point raised which I wish briefly to mention is the question of apportionment of liability. Perhaps those who drafted the report do not know that we have approximately fifty laws dealing with workmen's compensation and there are very many treatments as to just how liability is to be apportioned. Recommendations of the medical profession are useful and interesting and quite valuable, but there again the question of just how liability should be apportioned is not strictly a medical problem. It is one of legislation. While it may be advisable in certain cases to limit liability, from labor's point of view we want liability not to be apportioned. We want liability for the entire duration of the man's disability, as long as the disease contributed to the disability. Of course, there are certain practical limitations to that, but let me assure you that as long as you have good administration of an act you do not have to write the limitations into the act. The problem is one of administration, one of understanding, and is not one strictly of drafting legislation.

MR VERNE A ZIMMER, Washington, D. C. Administratively it would be almost impossible to apply the theory in this report. We ought to evaluate or appraise how important this particular subject is in relation to the whole workmen's compensation scheme. Experience of twenty years in two or three of the jurisdictions in this country that have carried on under all inclusive occupational disease legislation shows that at the very most occupational disease does not produce more than 4 per cent of the total cost of workmen's compensation. That is not a tremendous problem. There is probably less difficulty on the whole for administrators of workmen's compensation to administer occupational disease cases than accident cases. You would think that one would require practically all the medical talent of the state in order to adjudicate a case of lead poisoning, dermatitis or some other commonly accepted occupational disease. That is not true. Very few jurisdictions have an array of specialists in allergy at the beck and call of the administrators in order to break down and classify those types of allergy. Actually in practice no jurisdiction will get enough volume of cases attributable to allergy to warrant any such attempted administrative refinement.

DR D. J. GALBRAITH, Toronto. I agree with Mr Zimmer that, from the administration standpoint, occupational disease does give very little trouble. The percentage is small, and with careful medical investigation of these cases we do not consider they are at all a serious problem, not nearly so much as accidents. I can agree with the chairman's early statement that medical evidence given before medical men does vary widely from medical evidence given to laymen. I think that has something to do with minimizing our troubles.

DR HARRY LEE HUBER. This is a first report primarily as a guide and as a starting point from which we can work. About 10 per cent of those who are employed probably have some problem of allergy. Whether it is something that incapacitates them or not is a question. The word "suffering" as used means that these patients are incapacitated or partially incapacitated.

Control of Medical Testimony The Minnesota Plan

DR ERNEST M. HAMMES, St. Paul. In July 1940 Dr B. S. Adams, president of the Minnesota State Medical Association, called a joint meeting of some members of our association and of the Minnesota State Bar Association to discuss the problem of unethical expert medical testimony. At that time it was felt that attempted legislative measures had improved but not solved the problem. A committee was appointed by the president with the approval of the counsel of the Minnesota State

Medical Association. The committee was empowered to review those court cases in which medical testimony appeared to the court or to the attorneys or to some physician to have been so contradictory as to indicate that one or more of the medical witnesses appeared to be consciously deviating from the truth. The medical testimony under scrutiny was not to be confined to any particular type of legislation or to any particular court. It included all civil, criminal and personal injury cases and all cases tried before the industrial commission. The committee on medical testimony consisted of five members representing the various sections of the state. At their first meeting they determined the following policy:

- 1 That the judge or attorney or accusing physician must submit in writing a brief statement to the committee, giving the name of the physician to be investigated, and also the names of the principals of the trial, in order that a transcript of the entire testimony may be obtained.

- 2 That a transcript of the entire testimony of the case in question must be obtained and placed at the disposal of the committee. Only by this method will the committee be able to obtain a true knowledge of all the facts and assist it to arrive at an unbiased and just opinion.

- 3 To assist the committee, members of the state association in the various specialties must be willing to appear before the committee when requested to do so and express their opinion regarding the testimony in question.

Repeated complaints about medical testimony have been reported to the members of the committee but the accusing physicians were not willing to submit them in writing because of possible embarrassment. To obviate this the committee decided this year to keep the name of the accusing individual confidential.

The expense incurred to obtain a transcript of a three day trial in district court is approximately \$100. In the industrial commission a similar transcript will cost about \$75. The council of our state medical association has approved these expenditures. The committee has deemed it advisable to ask three outstanding specialists in the question involved to assist the committee in the investigation of a case. Their willing cooperation, sound judgment and unbiased advice have materially lessened the responsibilities of our committee. We also have the assistance of our state medical society attorney to avoid any possible legal complications.

Our committee has no disciplinary or judiciary power. In cases in which the testimony was of a mildly questionable character, more due to ignorance or overenthusiasm, the committee deemed it advisable to have one of its members discuss the problem with the accused physician and point out his delinquencies. This has proved satisfactory.

In cases of a flagrant character our committee submits a complete report with transcript to the state board of medical examiners. This board has judiciary power and can suspend or revoke the offending physician's license.

The late Associate Justice Royal A. Stone of the Minnesota Supreme Court suggested that this new plan should be given statewide publicity. Articles were published in the leading newspapers and news services throughout the state. Editorials have appeared frequently in our state medical journal. A detailed outline of this new undertaking was sent to every member of the state medical association and to every judge in the courts of our state. It was felt that the existence of such a committee would have a beneficial effect on the few medical men in our state who needed some guidance in their expert medical testimony.

In 1940, 1941 and during the spring of 1942 our committee received repeated complaints regarding medical expert testimony in our courts. Some were found unwarranted. The most satisfactory result noted is that during the present fall term of court not a single request has been made to any member of our committee to investigate the testimony of any medical witness. This, to say the least, is very encouraging.

J. W. Holloway Jr., director of the Bureau of Legal Medicine and Legislation of the American Medical Association pointed out to Morris B. Mitchell, chairman of the committee of the judicial council of the Minnesota State Board Association,

that unless consideration should be given to the crooked lawyer as well as to the crooked medical expert little could be anticipated from this program. He proposed, in order to get down to the roots of the evil, that the bar association appoint a committee to which could be referred all cases that are called to the attention of the medical committee, with the idea in mind that if it should be found that the attorney who proffered the suspected testimony did so with a knowledge of its falsity then he should be disciplined along with the medical expert witness.

The Minnesota state and the local bar associations have committees to which our committee can refer any questionable case for investigation and disciplinary action. The judges of the supreme and district courts, as well as the members of the bar association, have been very cooperative and our committee greatly appreciates their assistance.

This program of the committee has been outlined in detail because of the many requests we have received regarding its inception and method of functioning.

DISCUSSION

DR. RAYMOND HUSSEY, Baltimore. These committees in our medical society organization are extremely important. I presented the matter to our council in Maryland and asked it to consider the possibility of having such a committee in our organization. The council took it up with several of the justices in the courts of Maryland and they decided they didn't want it, that is, the judges decided they didn't want it. I should like to ask Dr. Hammes if he has had testimony from workmen's compensation cases presented to the committee.

DR. ERNEST M. HAMMES, St. Paul. Just one.

DR. DEAN CLARK, Washington, D. C. Can you give us an idea about what the volume of the work of the committee is and about how many cases you handle?

DR. HAMMES. We have had few cases, and those have been of a mild character. Many of the young men who get to court are afraid to say "I don't know" when asked a question. That is purely a lack of experience in court, much more so than trying to evade the truth. There is another group who feel that they must help the attorney win his case, and they become so overenthusiastic that they deviate just a little, probably unconsciously. Then we have those who are frank out and out. We had such a one that was referred to the state board of medical examiners. The board advised him that unless his attitude changed it would take drastic action. One case like that does wonders throughout the state.

Workmen's Compensation: The Shape of Things to Come

MR. HENRY D. SAYER, New York. Compensation laws are not identical. But there is one unfailing rule underlying all compensation laws—the rule that compensation will be paid regardless of fault as a cause of injury. The liability of the employer is certain, but it is not unlimited. Monetary benefits are fixed at limits that are measured by the loss of time or of wage earning capacity. They do not include what might be termed "punitive damages"; they take no account of pain and suffering, mental anguish or any of those other conditions that would be sympathetically urged on juries. And, in addition to payment for loss of time or earning capacity, the compensation system provides for the furnishing of medical and surgical care and treatment at the expense of the employer. This was not the obligation of the employer under the old employers' liability laws. His only liability for medical care was in case of a recovery for damages by the employee, who might in such case include in his suit the value of the medical services for which he had obligated himself.

The compensation laws have been declared by the courts in many states to be beneficial statutes, that is, they are recognized as having been enacted for the benefit of the workers, and as beneficial statutes the courts will strive to give full effect to their beneficial provisions and will interpret them liberally. Public opinion and policy will demand that all who have any duties under those statutes shall do their full part to make effective their beneficial provisions. Among the groups whose

participation in the system is essential are the employers, the insurance carriers and the physicians. The interest of each group is different, yet they have much in common. The employer, of course, has had a keen interest in compensation right from the first. The insurance carrier too has been keenly alive to its rights and obligations under the law.

From the first day of the law and from the first occurrence of an accident, the doctor has been a force to recognize. Doctors are commonly inclined to resent the making of paper reports to employers or insurance companies and to the public authorities. The first questions that naturally arise in the mind of the insurance examiner are: Who is the doctor, for what is he treating, how long will disability extend and what will be the ultimate result? On the true answers to these questions depend in large measure the position of the insurance company toward accepting liability and determining the preliminary reserve to be set up on the company's books, so that the money to pay the claim to its ultimate may be set aside and always made available. Thus is not only the obligation of the company under its policy contract but is also its legal responsibility under the insurance laws of most states. Continuing reports of disability provide the basis for continuing payments of compensation. Thus reports are a prime necessity if the compensation law is to be fairly and adequately administered.

If a doctor would practice his profession in the industrial medical field, there are many things that he must do. He must be something of an engineer, for his talents must be employed in an advisory way in the prevention of accidents as well as directly in the treatment of injuries after they have occurred. He must know something of industrial processes and methods, otherwise the histories he obtains from injured workers may sometimes be unintelligible to him or may lead to wrong conclusions. He must be something of a statistician if he would attempt to draw conclusions in regard to types of injuries and their causes and their end results. And today the industrial doctor must be something of a public and industrial health expert.

As originally introduced in this country workmen's compensation laws were generally limited in application to accidental injuries, just as the law was originally in England. But early in the compensation era there began a movement to provide compensation for disability or death due to occupational disease. In some thirty or more states there is now coverage for occupational diseases in some form. Compensation for specific occupational disease is the natural corollary of compensation for accident without fault. The assumed risk of accident in a hazardous employment, having been abolished as a defense in compensation, there would seem to be no good reason to permit the inherent hazard of diseases to be a bar to compensation for sickness or death from a disease that is a characteristic of the employment. It is reasonable to expect that as compensation laws shape up in the future they will in time all provide coverage for industrial diseases. Almost insuperable difficulties in defining the coverage of the law for occupational diseases have been encountered, however, because of the impossibility of exactly defining the term "occupational disease." Not all diseases affecting or acquired by workers are occupational diseases, not even all diseases that occur in the course of employment. That cannot be too strongly emphasized. Nor is an occupational disease law to be regarded as the employer's contribution to a general health law for workers. In an effort to define and delimit properly the occupational disease coverage there have developed two general methods, one the so-called "schedule law," and the other the "open" or "all inclusive law." The schedule law sets forth in a list embodied in the law all the diseases or disease conditions for which liability is sought to be established under the law. These diseases are frequently related in the law to specific working conditions or processes in which there is a characteristic hazard of the specific disease. Thus, for example, lead poisoning is a disease occurring among men who work with or handle or are exposed to lead in some form. If a man who works with lead develops lead poisoning, it will be conclusively presumed that he got the poisoning in his employment. If a person, however, develops lead poisoning and

it is conclusively shown that he does not handle lead or work with it and is in no way exposed to lead or lead fumes, it cannot be said that his lead poisoning is an occupational disease, and it must be caused by some exposure outside his employment.

What has been said of lead may be said equally of arsenic, mercury, benzene and any of the other toxic or harmful substances enumerated in the law.

The other common method of providing coverage for occupational diseases set forth in some laws is the general or all inclusive coverage, under which method specific diseases or disease conditions are not named in the law, but the law provisions include occupational disease by vague, general language or by attempted definition. I say "attempted definition," because there is no such thing as a standard or exact definition. Seemingly, this type of law would be more easily administered, for the administrative authority would not seem to be bound by the rigid restrictions and limitations of the schedule form of law. But that is not necessarily the case, as there are other tests that must be applied when diseases do not fall within the common category of "occupational." Such common and deadly diseases as pneumonia, tuberculosis and heart disease occur among workers just as they do among the nonindustrial people. When then if ever, may such diseases be regarded as occupational? The questions that may arise in connection with such diseases are difficult and may lead to long, expensive and discouraging litigation. In the one case both employers and workers are fully informed of the disease conditions for which the one is permitted to claim and for which the other is liable. The coverage is not so broad, because of its certainty and definite nature. In the other case the coverage may be theoretically more broad, but it is shrouded in such vagueness and uncertainty that the right to compensation may not be determined until after lengthy hearings and protracted legal process.

These seem to be the alternatives that present themselves in the development of occupational disease legislation up to the present time. The medical profession can contribute to the study of the fairest and most satisfactory method of providing coverage for occupational diseases in the shape of things to come. It is a question that should not be left wholly to the lawyers or to the industrialists or to labor, although the views of all these parties must be taken into account. Those views should be based on informed opinion, and the information to be supplied by the doctors could be most impressive. The great problem, the real problem of the future, is not in the payment of money benefits. It is in the prevention of accidents and the furnishing of healthful working conditions. Great strides have been made in the field of safety during the past twenty-five years. That field is the particular one of the engineer. Insurance will fail industry which it serves, medicine will fail the public to which it owes endless allegiance, if they do not work together for the solution of these problems.

Practical Problems in Framing Occupational Disease Legislation

ROUND TABLE DISCUSSION

DR KENNETH MARKUSON, Lansing, Mich. The workmen's compensation act in the state of Michigan is entirely under the administration of the Michigan Department of Labor. At the present time Michigan has a schedule law of thirty-one diseases. In my opinion it is not a good law, because there are certain inequalities. A workman has to be extremely fortunate to be exposed to one of the thirty-one scheduled diseases. The proposal which I believe will be presented at the present session of the legislature is for an all coverage law. I think that is a fair law if properly administered, but I do feel that there should be proof of exposure along with clinical findings. The law as it now stands provides payments for medical care for a period of ninety days. Many of the industries are paying for continued medical care, feeling that it is their responsibility although not a legal one. After the present emergency, when the labor market is going to be much more open than it is today, a lot of men are going to be out of work, principally on account of compensation laws. The man with physical defects, with mental defects, whatever they may be, is going to be denied employment.

DR BARNEY J HEIN, Toledo, Ohio. Ohio has an occupational disease law. It was passed in 1939 and it was the result of several court decisions by the Ohio Supreme Court, in which certain occupational diseases were recognized. This law specifies twenty-two different diseases and then goes on to say "All other occupational diseases." An occupational disease is a disease peculiar to the particular industrial process, trade or occupation and to which an employee is not ordinarily subjected or exposed outside of or away from his employment." That certainly takes in everything. In the way of administration, the Industrial Commission of Ohio has a silicosis board consisting of three doctors, one a roentgenologist, another a specialist in chest diseases and the third an internist. Cases of silicosis are referred to this committee. Questions about other occupational diseases arise so a list of doctors has been selected throughout the state based on qualifications. They are selected by the dean of Ohio State University, the Industrial Commission of Ohio and by the department of health. Any employee has a right to appeal to this board for final discussion.

DR HUSSEY. In Maryland our law states that the medical board is to investigate and hear controversial medical issues. We actually go into the plants and see for ourselves what the situation is. We accomplish the same thing that we do in hospital wards when certain clinical situations demand study and we call on consultants. We cannot be physicians and cover all the other technical fields. We must have the cooperation of the engineer. We must be possessed of sufficient knowledge to direct the effort of the engineer. The engineer is helping us, not directing us. Because relatively few men have realized that situation the engineer has taken the initiative. We cannot define occupational disease. The subject of nosology in medical science embraces the classification of disease. The basis for the classification of disease is etiology. As we understand the pathogenesis of the disease we are in a position to express an opinion. Our economists, our legislators and our employers must provide the means for the proper care of the workman, but it is up to the medical persons to decide what the disease is, what the etiology is and whether that etiologic agent is one that is associated with the processes involved in his work. The difficulty arises in getting the facts and fitting those facts into the definition of accident. In medicine etiology is the basis of our knowledge of disease, and injury is any change that takes place in the body as a result of the effect of an etiologic agent.

DR D J GALBRAITH, Toronto. In our setup there is no appeal from the decision of the board. We administer the act. Appeal is not allowed on point of law or fact. Medical aid is entirely in the hands of the board. We feel that the entire responsibility for the injured man is ours from accident prevention through his medical care and treatment, until the man is back on a job again or is compensated for the loss which he has sustained. Under an act of that kind, many of your difficulties are removed. We have still the schedule type of occupational disease coverage. We would rather have the blanket coverage, but under the act as we have it we have a great deal of leeway. We can call these conditions accidents and as such we have found that both the employers and the workmen readily give approval. Our government some years ago came to the conclusion that the majority of the problems that came before a workmen's compensation board were medical problems, and as such they felt that a medical man should be placed on that commission. When the next vacancy arose another doctor was appointed, so that we then had a commission composed of a manufacturer, an industrialist and two physicians. There is now a vacancy on the board. In administering an act of this kind, medical men have an advantage. You have injured men. You have men suffering from industrial diseases. Every x-ray film in the province of Ontario is sent to our board immediately and is examined by the most competent radiologist in the province. If he finds that postoperative films do not show adequate reduction he takes the film immediately to our chief surgeon whom we recently appointed because we felt that he was one of the outstanding orthopedic surgeons in the country. Between them they decide what should be done for that man and it is done.

We remove the patient definitely from the hands of the incompetent doctor and put him in the hands of the man who we feel is most competent. The medical profession, with which this was discussed from one end of the province to the other, has so far given us nothing but kindly comments on the results. Some of the outstanding traumatic surgeons have made slips which we have discovered and brought to their attention. They thank us for it and generally commend the policy. We know that we shall get objections from the weaker men, the men who are not doing so good a job, but the medical profession, the Ontario Medical Association discussed this with me before the plan was put into operation and gave us the green light. Certainly there are advantages for the medical profession and for the workman himself. In the early days of workmen's compensation in the province the Ontario Medical Association appointed a Committee on Problems of Workmen's Compensation. The medical profession was to take all its grief to this committee and it was to present it to the board. Last year the chairman of that committee came to me beforehand, before the annual meeting, and he said 'I am going to have a very nice report this year. During the whole year there has not been one single complaint from the medical profession with regard to the work of the compensation board.' He said 'I think we shall have to dismiss our committee.' That is the committee you are talking about.

MR VOYTA WRABELTZ, Madison, Wis. In Wisconsin we have covered all diseases whether occupational or not, and the job of administration and the costs have been so small that we sometimes wonder what in the world you are arguing about. Certainly any disease I don't care what it is, if it is caused by any occupation, causes just as much wage loss, just as much hardship to the worker as if it were a typical occupational disease. There is no justifiable reason for merely placing on the compensable list only those diseases that stand out as typically occupational. We have covered in our law all diseases of occupation since 1919 probably an experience as long as any other state. The over-all cost for the past twenty-two years has been 3.3 per cent of the cost of all compensation for accidents and diseases. Certainly that isn't a terrific load. That cost probably is larger than it should be and than it will be in the future. We have met the problem frankly without attempting to leave out so called accidental disabilities and we met it at a time when it was really critical, at the beginning of the depression when symptoms were magnified much by lack of employment opportunities and every one regarded the problem somewhat in a hysterical state of mind. In our desire not to do harm we paid compensation in many cases in which not a cent should have been paid. Many cases were settled on the basis of partial disability, 20, 30, 40, 50 per cent that should never have been compromised at all. We know in the light of our experience today that there is hardly any such thing as partial disability in the case of silicosis. It is either a total disability or none at all. These cases were settled on an overliberal basis in the years 1933, '34 and '35. That problem will never be met again in Wisconsin. From the standpoint of prevention and of minimizing the effects of disease you may have to have some special approach to some special problem, but from the standpoint of compensation there is no reason for you to have a special chapter in your schedule books covering occupational diseases. Bring them in like any other disability. It is very essential that a really constructive program of physical examinations be instituted so that the rights of workers may be protected. But above all no compensation law should be written or any amendment put into the law in the belief that somebody is going to be incompetent or not have the proper concept of the law to administer it properly. Whenever we enact a law we should assume that the people who are going to administer it are competent and if they are not that is the fault of your state. You should develop a tradition of appointment to offices of this kind on a nonpolitical basis and administrators should be retained in office long enough so that they are familiar with the problems with which they have to deal and they should not be kicked out every time a new governor is elected.

MR SAMUEL KAITMAN, New York. What we need is some one who will be able to determine the question 'Is that disease due to the employment?' Is it to be done by having a doctor who perhaps knows how to determine that question from a medical point of view? Is it to be done by a layman appointed without political considerations and with sufficient tenure of office to be able to learn those determinative factors or is it to be done by a lawyer who might know the legal aspects and will have to learn the medical aspects? I don't care how it is done, but they must be able to determine whether or not that disease is due to the occupation. I don't care whether you have a schedule or whether you have an all inclusive occupational disease law, the crux of the situation is 'Is it due to the employment?' In New York we deal with any number of allegations of tuberculosis, heart disease and kidney disease. The whole gamut of systemic diseases is alleged to be due to occupational exposure. Some of them may be. I know from experience that many of them are not. The doctors can assist the administrators tremendously in making the determination as to whether the disease in question is due to the employment. We have heard some statistics to the effect that not very much is involved and therefore there is no problem. If there is anything we can do to eliminate those diseases which are due to occupation we must and should do it immediately. The salvation for the worker is in prevention. We as insurance carriers, you as doctors, the administrators of the laws, labor—all of us can get together and plan some definite action whereby first we determine what effects are due to employment and, secondly, we prevent them from occurring.

JANUARY 12—AFTERNOON

DR ROBERT T. LEGG, Berkeley, Calif., Presiding

INDUSTRIAL MEDICAL PRACTICE AND THE EMERGENCY

Correlation of Industrial Medical Organization with Community Emergency

DR WARD L. MOULD, Washington, D. C. When the national emergency was first declared by the President in 1941, he created the Office of Civilian Defense and made that agency responsible for the development of plans for the protection of life and property against enemy attack. This organization was to be correlated with the armed forces through a joint board representing the Army, Navy and Office of Civilian Defense. Plants manufacturing war material were made the responsibility of the Internal Security Division of the Office of the Provost Marshal General, and the responsibility was decentralized into the Internal Security Divisions of the nine service commands. The Navy likewise was given responsibility for plants in which it was concerned.

Because of the placing of responsibility in the Office of the Provost Marshal General, it is not surprising that the principal consideration in the internal security administration was in the policing and guarding of plants, and it is not surprising that, even in setting up programs to cope with disasters, again the emphasis has been placed on the security of information, the security of plant property and the security of records. Plans which were to provide for the care of people who might be injured in such catastrophes were deplorably weak. Plants have set up organizations designed to provide first aid for people who might be injured in catastrophes but they have failed to realize that no plant organization will make that plant self sufficient. That the minute anybody is so seriously injured that he requires hospitalization or the services of a coroner the plant has ceased to be a self-sufficient organization. It is necessary that there be a correlation between the plant medical department in planning for the care of a large number of injured people who might be injured in a disaster with the local organizations responsible for the care of civilian casualties due to air raids.

Recognizing the weakness of the internal security program as it applied to catastrophes the Office of Civilian Defense and the Internal Security Division in the Provost Marshal General's Office and in the nine service commands have worked out a

program jointly for adoption by plant medical departments where it is feasible. Certainly the plant medical department is not set up to care for a lot of seriously injured persons at one time. Its personnel is limited. The number of personnel even in a good plant medical department need not be particularly numerous to cope with the problems of industrial medicine, and if a large number of people are injured at one time the deficiencies of plant medical departments would be greatly magnified. Facilities are a little better. If one surveys industrial medical facilities one finds that very few plants have their own hospitals and that only 20 per cent of plants have made arrangements for the hospitalization of industrial accident victims. First aid rooms are provided in a goodly number of plants, but still there are about 30 per cent that do not have first aid rooms. Plants that have dispensaries are fortunate in that they then have a facility for the treatment of the industrial accident victim, but such rooms are not ordinarily adaptable to the care of a large number of people at one time. They are small. They are compartmented. They perhaps have an eye chart, a goose-neck lamp, an examining table, an examining chair and a couple of beds to one side where persons can be put for a little while until transportation can be arranged, but they are not ordinarily adapted to the care of many persons. So we have felt that an entirely different type of organization should be developed within the plant for the care of persons injured in a plant catastrophe.

We have conducted surveys of hospitals in cities to determine the possibility of their expansion of bed capacity, and not only in the cities themselves but in outlying areas, so that, in the event of an emergency, patients occupying city institutions would be evacuated to other communities, thereby making city institutional beds available. We have conducted, in cooperation with the Public Health Service, a program for the organization of blood banks in hospitals. Money made available to the Public Health Service and jointly administered by it and by the Office of Civilian Defense has been awarded to about one hundred and fifty hospitals for the creation of blood banks, in return for which the hospitals have agreed to accumulate 1 unit of plasma per hospital bed. In addition to this plasma, which is a steadily growing pool, we have bought outright from the processors dried and frozen plasma prepared from blood collected by the Red Cross. This plasma has been placed in strategic locations all over the country. Not every hospital, of course, has blood within its walls or in its pharmacy, but all hospitals have access to this blood through its local organization of civilian defense. While the blood is primarily accumulated and stored for the treatment of civilians injured in enemy action, it may be used in any emergency.

Because we have developed our organization along these lines, it was felt by the Office of Civilian Defense and by the military authorities that, where the organization was properly and well developed, with the facilities available in the community and under the central administrative direction of the local chief of emergency medical service, if the plant medical department and the community emergency medical service could get together and work out a joint program of mutual assistance, much confusion might be avoided in the event of a plant catastrophe. Of course, the whole civilian defense program at the local level is a volunteer effort, and it is to be expected therefore, that the development of our program is spotty, but for the most part there has been a pretty good development of emergency medical service.

The plan that is developed by the plant medical department in cooperation with the local emergency medical service should provide for two contingencies: first, a catastrophe which is localized within the plant, in which case all the resources of the community can be made available to the plant, and it should also provide for a catastrophe in which the plant and the community are involved, in which there has to be an apportionment of medical service between the two. The plan should provide for the hospitalization of people who are injured. It is necessary, in the administration of such a responsibility as the hospitalization of people, that patients be spread through as many hospitals as possible so that one is not going to be overloaded while others are twiddling their thumbs. The plan should also

provide for efficient ambulance transport which in many instances has been pretty well tied together by the local emergency medical organization, and in communities where our organization has been well developed the local chief has not only surveyed the facilities which are available in the community but has determined the possibilities for the emergency expansion, by the conversion of panel-body trucks, and other similar vehicles.

One point that causes, I think, an undue amount of confusion in catastrophes is the matter of identification of casualties. In any plant disaster a careful record must be kept not only of people who are injured but of people who are uninjured who leave the plant. Unless this is done it will be a very difficult matter to determine the number and the names of the missing.

The identification badges that are used in most plants will assist materially in determining the identity of people who may be unconscious. Too frequently one finds that in the administration of first aid in the plant medical department or in the plant yard or at some point the patient is very carefully disrobed, and with his clothes go his identification badge. He is transported in an unconscious state to an unknown hospital in an unknown community. In a recent episode to quote a specific example, three weeks after the catastrophe patients were turning up who were presumed dead. They had been transported in unknown numbers to unknown hospitals in unknown cities in unknown ambulances. While this did not detract necessarily from the quality of the medical care which they received it certainly did not contribute to the improvement of public morale.

Another phase of catastrophe planning which is frequently overlooked is that inevitably some people are going to be killed if the catastrophe is of any consequence, and we fail to make provision for people who are killed. There should be a room designated to which they can be taken and left until arrangements can be made for transportation to mortuaries or morgues. While it is not necessary that they be identified before they leave the plant property, it is necessary that all identifying data should be on the person when the body is moved.

Our civilian defense scheme of emergency medical service does not differ materially from the program of the Army in its care of casualties. We feel that treatment on the spot is very necessary and that that treatment should be given by qualified persons.

In order to filter the casualties, to prevent an overload of patients with minor injuries and patients with hysteria arriving at the admitting office of the hospital, we have established what we call casualty stations where these lesser degrees of injury can be cared for. The casualty station is ideally a big open room. It is not equipped for surgical procedures. It is set up primarily for the administration of first aid and the care of minor injuries.

We fail frequently to consider the importance of sanitation services in plant catastrophes, and yet dangers to community and plant sanitation are inherent in all disasters. Explosions that will cause fractures of water mains and sewer pipes, fires, fire fighting operations, may cause such a drop of water pressure as to cause a back siphonage of sewage into potable water supplies. Many plants have their own water supply which is independent of that of the community, and frequently it is not a potable supply. All of these things must be taken into consideration. Following a catastrophe of any degree at all it would probably be wise to obtain the assistance of the sanitary engineer of the local health or water department to determine whether there is a sanitation hazard in the plant as a result of the accident.

One thing which we have been working on diligently in the Office of Civilian Defense is the matter of admission of physicians to assigned plants, an assigned plant being one which has been turned over to the War or Navy Department for the security of the plant. Visiting in such plants is rigidly controlled, and properly so, but in November the War Department emphasized its stand on visitors' clearance and placed responsibility for the admission of personnel on the plant management but said that special provision should be made for the admission of policemen, firemen and physicians to the plant in time of disaster. We have been working with the various service com-

mands to develop a procedure whereby selected members of our organization, of our local organization, would be identified, following investigation by the service command, by passes that would be issued by the Office of Civilian Defense and countersigned by the security officers of the War Department.

Last, but not least, is the matter of responsibility for people who are injured, who are carrying on civilian protection duty in plants. I know plants which have several thousand men engaged in plant protection activities and the activities are in some instances hazardous. Auxiliary firemen, in their tramping, climb up ladders, scale walls and so on laying themselves open to accidents which will necessitate medical care and hospitalization. Some categories of plant protection workers—when I say that I am not referring to guards—are employees during the time they are carrying on their plant protection activity. The Wage and Hour Division of the Department of Labor has ruled that if the activity is carried on during the usual working hours of the employee, he must be paid wages for his activity, and, if he is paid wages, it is presumed that he will be covered by the compensation law obtaining in the state. If he carries on his activity outside his regular working hours, in some instances he will and in some instances he will not be an employee for whom wages must be paid, depending somewhat on who the directing agency is within the plant having charge of the civilian protection activity of the plant. If he is a member of the local citizen's defense corps, which is the protection organization of the community under the Office of Civilian Defense and he is assigned to the plant he will not be an employee of the plant, in that wages do not have to be paid for his activity as a civilian defense worker. In February of last year a special allocation was made from the President's Emergency Fund to the Federal Security Agency to provide for the medical care and other benefits to civilians who were injured as a result of enemy action. As no specific provision was made for civilian defense workers, no coverage was furnished such persons during drills and exercise, though they would be covered in the event of injuries sustained in an air raid by virtue of the fact they were civilians. To provide for financial protection and medical care for civilian defense workers injured in training exercises and other drills of the Office of Civilian Defense, a supplemental allocation was made, to be administered by the Federal Security Agency. The manner in which this fund is to be administered has not been completely worked out, but the regulations which are now being prepared will, I think, be very specific in providing assistance to members of the local citizen's defense corps who may be injured while on active civilian protection duty. While there may be some adjustment made for people engaged in such activities but not actually members of the corps, I don't think that any specific provision will be made for such situations. We feel, therefore, that it is important that people who are engaged in passive plant protection as auxiliary firemen, auxiliary policemen, air raid wardens and so on, be made members of the local citizen's defense corps so, in the event they become injured in the performance of their functions they will be covered by some type of program insuring medical care and certain other disability benefits.

The Health and Safety Program of the U. S. Maritime Commission and the U. S. Navy in Contract Shipyards

MR. PHILIP DRINKER, Boston. This article appears in full in this issue, page 822.

DISCUSSION

DR. DEAN A. CLARK, Washington, D. C. Can you tell us something of the way in which the unions were brought in on your industrial health and safety plans?

MR. PHILIP DRINKER, Boston. The survey we made last summer was first suggested before the so-called Ship Stabilization Committee meeting in New York last July. At that meeting were representatives from the government from the labor unions and from management. Labor knew of the projected survey last summer. They all expressed approval. When we had made the rounds, I met again with the C. I. O. and with the A. F. of L. and told them the results of the survey and the

essential recommendations and changes we were going to ask for. We were perfectly frank with them. We told them that one of the things we thought was not handled properly was the total lack, in some districts, of preplacement physical examinations. Literally there are none. We told them why we wanted them. They agreed that a change was in order and should be made, which was quite a revolutionary step. How quickly we can put through the benefits of that change in attitude has yet to be proved, but we have every hope it will be. When we survey the yards, yard by yard, we don't always get in touch with the union men because of the time that that would consume, but we take care that the unions themselves know we are coming. There hasn't been a single step in any of this but that the union has been appraised fully.

STREAMLINING INDUSTRIAL MEDICAL SERVICE

How to Get Along with Less Help

DR. EDWARD C. HOLMSTAD, Chicago. This article appears in full in this issue, page 820.

Outline of Procedure for Nurses in Industry

A report of the Council on Industrial Health, American Medical Association, presented by Dr. Orlen J. Johnson, Chicago, will appear in full in THE JOURNAL.

Putting Your Medical Records to Work

DR. M. H. MANSON, New York. If some aspect of the work must suffer it is usually the records. The prospective employee should encounter the physician first in industry and does so in many instances. It is difficult to estimate at the present time the percentage of workers in industry who receive preplacement examination. In 1932 the American College of Surgeons reported preplacement examinations in 63 per cent of 925 industries studied. In 1939 the National Industrial Conference Board 84.4 per cent and in 1940 in a study made by the National Association of Manufacturers, 72 per cent was reported. With thousands of people being added to payrolls practically overnight the number of preemployment or preplacement examinations now is considerably less than the incidence indicated in these studies.

What can we learn from the results of preemployment examination and to what use can we put this knowledge? With few exceptions there are no analyses made other than a percentage calculation of rejections, which varies from 2 to 5 per cent in most industries in normal times. We have gained considerable information about the physical status of a specific group of our population as the result of analyses of selective service examinations both in the last and the present great war. These data are not comparable to standards and methods of examination in industry, nor are they as inclusive in scope, considering industry's wide spread of age groups, racial differences and sex differences. Much significant information is buried in the medical files of industry concerning the medical status of our population at the time they enter employment which should be currently and periodically analyzed and compared. Wider usage of preplacement medical records will give us a base line of incidence of actual or incipient medical conditions for specific industries for which these industries will ultimately pay millions of dollars either directly in sick and accident benefits or indirectly as a result of lost time. A compilation of such information would also provide a more accurate picture of the nation's health geographically than some widely quoted studies such as have been made by WPA workers. I should like to see some group sponsor and provide the mechanism for uniform studies and compilations of similar data. Work sheets for this purpose are simple to devise and put into use.

Development and morbidity of newly arising conditions should be similarly studied by tabulation and analyses through periodic health audits of individual employees. The term health audit is used because a periodic medical appraisal is, or should be, far more than a physical examination. Work sheets identical with, or similar to, preplacement analyses may be used to facili-

rate comparisons. The 1941 report on industrial health practice made by the National Association of Manufacturers indicated that only 21 per cent of the 2,064 industrial establishments studied conducted periodic physical examinations. According to some observers cardiovascular diseases occur with undue frequency in occupations which demand severe physical exercise. The most recent and perhaps only study of death rates by occupations was that made by Whitney in 1936, which revealed that the rate for males from all causes, corrected for variation in age, was 623 per hundred thousand for agricultural workers, 775 for clerical workers, 829 for skilled industrial workers, 1,009 for semiskilled industrial workers and 1,448 for unskilled workers. This undoubtedly indicates a field for some detailed study as to causes and methods of prevention, and further continuous studies of a similar type are certainly indicated at the present time.

Sickness is responsible for about 85 per cent of absences, off the job accidents approximately 10 per cent and on the job accidents 5 per cent. Illness causes fifteen to twenty times as much absenteeism and about seven times as much lost time from work as industrial accidents. Reflecting that industrial accidents are responsible for about one billion five hundred million man hours loss of production each year, the importance of illness is tremendous. Absenteeism is greater following holidays and at the beginning of hunting seasons and is decreased on pay days and days when overtime rates are in effect, and it is often reduced by the mere knowledge that a study is being made of the subject. Absenteeism is greater in plants where employees are paid for all absences. In one shop the rate increased over 300 per cent when pay was given for the first two days of absence. I do not believe that there is any one answer to absenteeism.

Illness absences are said to be at least three times more important economically than the actual number of days lost because of reduced efficiency in the developmental and recuperative stages of the illness. It has been stated that every employee loses an average of nine and one-half working days each year, the rate being twelve days for women and seven days for men. With the increasing displacement of men by women in industry and the prophesied addition of thirteen million workers to plants manufacturing war material, the importance of the problem of absenteeism due to illness can well be visualized.

Before anything can be done toward solving this costly and vital problem, an absenteeism analysis is essential such as the report of studies in personnel policy (number 46) made by the National Industrial Conference Board entitled "Reducing Absenteeism." We in the New York Telephone Company employ the following procedure in cases of absenteeism due to illness. On the third day of any absence a representative from the disability bureau of our traffic department visits the employee (telephone operator) at her home. At this time it is ascertained whether or not the employee is under proper medical care and a medical certificate is left to be forwarded to our medical department by the employee's private physician. The visitor completes a report which indicates, if known, the nature of illness and other pertinent information. From this, together with a report from our medical department, a card index is built which indicates the frequency of absences and the nature of the disabilities. Every employee having six or more absences in any given six months period is referred to the medical department for special examination (this is termed a frequent illness visit and is obligatory) to determine whether or not any corrective measures are indicated and for advice on general or specific health problems. The value of keeping a constant check on absences may be better visualized by considering a plant employing ten thousand workers, forty-eight hours a week. They can expect a loss of approximately eighty thousand man days this year, or two hundred and eighty employees absent every day. If the plant is employing more women than usual or inexperienced men, the loss will be one hundred thousand man days, or three hundred and fifty absences each day.

The question of toxic hazards and exposures is of paramount importance because of the continuing use of substitutes and new materials in manufacture. The apparent interruption in the downward trend of tuberculosis certainly deserves careful consideration.

The work of the medical department is divided into two categories, administrative and diagnostic. A code is used for the various subdivisions in each category. Administrative coding makes provision for tabulating preplacement examinations, employee examinations of all types, accidents, sickness, consultations and other interviews, x-ray examinations, laboratory examinations and other services such as injections or treatment, the latter either at the behest of the employee's private physician or of an emergency nature. The diagnostic code makes provision for diagnoses according to systems, such as respiratory, digestive, genitourinary, endocrine, circulatory and special sense organs, plus a diagnostic classification for injuries. The combined coding is transferred from the individual employee record to a work sheet on which is also indicated other information such as original or repeat visits and the disposition of the patient. This information is then transferred to punch cards by means of the Hollerith machines. At any given period these cards may be sorted to obtain any desired combination of information. For example, one may compare the number of absences for more or less than seven days due to influenza or any other illness for any given period. This method of tabulating the experience of the medical department has been desirable and helpful.

We need more and better medical records, more widespread use of these records applied to our problems in industry, and improved interchange of experience to aid production.

Processing Industrial Physical Examinations

DR FRED B WISHARD, Anderson, Ind. This article appears in full in this issue, page 810.

DISCUSSION

MEMBER. I should like to ask Dr Wishard about the expense of the examination, if it has ever been figured out.

DR FRED B WISHARD, Anderson, Ind. We never figured it out. We have made some calculations with regard to our total cost. I think it runs about 6 or 7 cents, but the amount of the examination would be, roughly, \$2. It costs 97 cents to use, process and store a 14 by 17 x-ray film.

MEMBER. What percentage of women do you examine in relation to men? Do you have a duplicate setup or can you use the same one?

DR WISHARD. We don't examine women to any appreciable degree. We do check vision, chests, blood pressure and a blood test.

MEMBER. Do you do urinalyses on your preplacement examination?

DR WISHARD. We do not. We probably would be better off if we did.

Resuscitation: A Review and Demonstration

DR HART E FISHER, Chicago. A demonstration of lantern slides.

JANUARY 12—AFTERNOON

DR RAYMOND HUSSEY, Baltimore, Presiding

SYMPOSIUM ON REHABILITATION

Rehabilitation—Recent Developments in Connecticut

DR JAMES H BIRAM, Hartford, Conn. We have had in Connecticut since 1920 a vocational rehabilitation service which supplemented workmen's compensation and had for its object the training of injured employees and fitting them again for industry, and in supplying artificial appliances and training in their use. Somewhat over a year ago clinics were established in conjunction with the State Medical Society, the Manufacturer's Association of Connecticut and the Departments of Psychology at Yale and Trinity. Handicapped individuals were evaluated and were presented before groups of manufacturers or their representatives. This was not a true rehabilitation program but more for reeducation and job placement, depending on interested charitably inclined employers. With the shortage of labor, most of this group were placed. This plan found

employment for a considerable number of handicapped individuals. One day last September I received a call from the employment office and found that on that day it had one hundred and fifty requisitions; that fifty-four had applied for work and my examiners had turned down twenty-four and had taken waivers on most of the remainder. On investigation I found that ten had been rigidly rejected for machine jobs because of varicose veins. I arranged time to examine all questionable rejections and found that varicose veins was second in causes for rejection just below cardiovascular disease and above visual defects. A considerable proportion of these could be salvaged by the simple operation of ligation and injection of the saphenous vein.

How was this to be accomplished? It was not entirely the manufacturer's responsibility nor the state's, as these people came from all over the country. After unsuccessful attempts to interest various groups in this venture I finally called Mr. Edward Chester, director of vocational rehabilitation at the state board of education, and stated the trouble to him. In a few days a meeting attended by fifty representatives of various organizations was held. The representatives were informed as to our undertaking, shown its need, and invited to express their opinions. Because each group saw that this venture vitally affected them there was complete cooperation.

Mr. Chester, as director of rehabilitation in the state, was authorized to serve as chairman of a committee and to appoint a small advisory committee, each member of which was to be chairman of a larger group representing his special interest. It was decided that each committee was to meet the following Wednesday morning at the Hartford Club and have a definite proposition ready so the chairmen could meet that same afternoon to plan for carrying out the program. This was done, and the Connecticut Wartime Manpower Rehabilitation Committee started to function in its advisory capacity to the Rehabilitation Division of the State Department of Education.

At this meeting it was determined:

A. That at present only defects in the preemployment group that needed relatively short treatment or evaluation should be attempted. As a guide the following conditions were named: (1) cardiovascular disease, (2) varicose veins, (3) hernia, (4) vision, (5) minor orthopedic defects, (6) diabetes, (7) miscellaneous.

B. That candidates for rehabilitation were to come from: (1) plant physicians, (2) rehabilitation offices set up in the different industrial centers of the state, in this case plant physicians or a group of consultants would determine the advisability of making a correction of the disability.

C. That a statewide panel of doctors be set up to secure competent men to carry out the necessary procedures. That names for consideration on this panel were to be submitted by: (1) plant medical directors, (2) medical directors of the insurance companies, (3) hospitals, (4) specialists. Workmen's compensation rates should govern the fees paid to doctors for services rendered.

D. That hospital rates were to be their lowest semiprivate charges.

E. That the client should have the choice of hospital and panel doctor.

F. That medical and hospital bills be paid by the Rehabilitation Division of the State Department of Education and that the individual make repayment to them on an instalment basis. Also that inability to pay would not disbar any one.

Expenses were to be met by a revolving fund, furnished one half by the state of Connecticut and one half by the United States.

This program was at once put in effect in Hartford County on an experimental basis, and after a month's trial during which time a panel of doctors and hospitals was set up it was established on a statewide basis. At the time this paper was written too short a period has elapsed to speak of accomplishment.

It will be interesting and instructive to see how this works out now that it is on a statewide basis, but I am sure that the same enthusiastic response to a need that started this work will carry it on.

We in Connecticut believe in state rights. We will welcome all governmental advice and help that is offered, but we believe that with the earnest and hearty cooperation of the state agencies, the medical societies and hospitals and with the backing of the manufacturers, the compensation commissioners and labor that we can take care of our rehabilitation problem without regimentation.

DISCUSSION

DR. WILLIAM ARKWRIGHT DOPPLER, New York: In Connecticut they are quite successful in handling the tuberculous. Have you run across any situations of that kind?

DR. JAMES H. BIRAM, Hartford, Conn.: We have in the plant now fifteen or twenty known cases of tuberculosis.

DR. HUSSEY: Can you say anything about this work in relationship to the waivers that Connecticut is so noted for in its compensation act?

DR. BIRAM: If we couldn't take waivers on some of these conditions we wouldn't feel that it was fair to the company to take these people in. Maybe we do run high in waivers, but most of the sizable plants now have a medical director and a medical staff. They make preplacement examinations.

DR. HUSSEY: What force does the waiver have actually, if there is a test of it in a legal procedure?

DR. BIRAM: There never has been a test of the waiver in Connecticut in all the years during which it has been in operation. I don't see why a waiver isn't perfectly justifiable. When you have a plentiful choice of men it may not be, but when you're down to the dregs, as we are in Connecticut, I think a waiver is perfectly justified.

DR. HUSSEY: It is my understanding that the whole waiver plan in Connecticut was really initiated by labor.

DR. BIRAM: It was.

DR. JOSEPH H. CHIVERS, Chicago: Is there any implication on the part of manufacturers that a man will be given a job if he submits to the recommended treatment?

DR. BIRAM: Yes, we go over the man to be sure that he won't be turned down for any other cause and we obligate ourselves to give him a position in the plant. Of course, later on after this is over, it might not be possible to do that, but at the present time as soon as the man is said to be ready for work we look him over and see that he is and if so he comes to work the next day.

MR. H. E. CORFVONT, Lansing, Mich.: Do you have any state agency other than rehabilitation or a local agency that will be responsible for operative care or medical care of adults?

DR. BIRAM: Not that I know of.

MR. MARTIN DAILEY, Brooklyn: Is there any provision in this program for persons who have been employed for some time and who have had breakdowns or is this just for pre-employment?

DR. BIRAM: This is just preemployment. A great many of these men have been employed and have left one job and are seeking a higher paid job. We take anybody who is capable of rehabilitation and see what can be done with him.

DR. R. L. NICHOLS, Chicago: It has been said that people with major disabilities make better employees from the point of view of absenteeism than the normal. Have you found that true or not?

DR. BIRAM: I agree with that. Absenteeism in the factories now runs somewhere between 8 and 12 per cent. Labor turn over varies from 8 to 12 per cent, practically 100 per cent a year. These semidisabled people stay at work and do a good day's job and are thankful for their jobs. The average employee today if he can get 10 cents an hour more will leave you and go somewhere else.

DR. HARRIS POWERS, Manchester, N. H.: Is there any question of aggravation being brought up afterward?

DR. BIRAM: A waiver stands as far as any aggravation of the condition is concerned. You take a waiver on a hernia and the waiver will stand whether the hernia strangulates or not. We are not responsible for it.

CHAIRMAN HUSSEY Connecticut is the only state in the Union that has such a satisfactory waiver law. Is that true?

DR BIRANI The compensation act in Connecticut works very well. We have high grade commissions. It is the only court I have ever been in in which I thought any attempt was made to obtain justice.

DR C F YEAGER, Bridgeport, Conn. In the eight years that I have been affiliated with the Remington Arms Company we have never known an instance in which advantage of this waiver was taken. However, I do feel that we would have a moral responsibility in case of aggravation, if not a legal one and I am sure that we would take care of it.

Psychiatric Problems in Rehabilitation

DR ALFRED P SOLOMON, Chicago. If the physician decides that the patient is feigning or shamming, that his simulation is conscious or deliberate, he recommends that the patient be discharged from further compensation and medical care and that he return to his work. In most instances he does not anticipate that his attempted disciplinary action will immediately rehabilitate his patient.

It is a human trait to want to take things easy, to drop everything and take a long rest. The continuing disability payments in psychologically protracted convalescences encourage a satisfaction of this biologic urge. The alternative, a lump sum settlement, removes the parentalistic figure. However, paradoxically, the anticipation of this lump sum settlement often motivates the development of a protracted convalescence.

Large sums of money are spent each year for lump sum settlements when a diagnosis of traumatic neurosis has been made. I raise the question as to whether a much smaller sum of money could not be spent on a method of rehabilitation more psychiatrically sound both for the patient and for society as a whole. In this paper I will propose such a method. The method has four major divisions.

- 1 Psychologic understanding of the patient's character, in order to avoid emotional trauma to his personality during all his professional and industrial contacts.

- 2 Psychiatric evaluation of the patient's emotional problems, both related and collateral to his accident, in order to clarify the dynamic meaning of his attitudes and so that the patient may be made to understand his own behavior.

- 3 Careful supervision of all the psychologic aspects of his return to employment, so as to avoid maladjustment and if possible improve his previous work adjustment.

- 4 Instituting at the first evidence of psychologically protracted convalescence of a recreation and exercise therapy program supervised by psychiatrically trained physical directors.

With psychotherapeutic interviews alone, the average patient will require additional therapy. It has been my experience that because of the frustrations involved these patients will cooperate in a treatment which offers them diversion, recreation and play, good body development and amiable companionship, even if the acceptance of that treatment denies the further existence of the convalescence.

For the past thirteen years I have used the full facilities of a well equipped gymnasium, such as the Lawson YMCA, for this treatment. Best results were obtained with nonresidents of Chicago who lived at the Lawson YMCA, confirming a usual psychiatric observation that patients more readily recover away from the influences contributing to their behavior. The luxurious atmosphere of this particular institution is far above the average standard of living of the workmen I have treated. This enables the employer to be seen as one who is generous rather than one who takes and deprives. The patient is carefully instructed in the indications for and the nature of the treatment. His cooperation will depend on his confidence in the assisting therapist as well as that of the physician. An athletic companion is selected who must be skilled in sports, a leader, decisive, resourceful, tolerant, sympathetic to the patient's resistant behavior, interested in a therapeutic result, able to comprehend a psychologic explanation and to follow orders. He should be

able to motivate the patient by gaining his confidence, maintaining control of the situation at all times, be able to engage in competitive games, winning or losing at will, be able to teach the patient athletic skills, and to show enthusiasm and gratification at the patient's successful performance. On sight seeing excursions, on long walks in the parks on visiting places of interest and amusement, he should be friendly, companionable and appropriately enthusiastic.

The patient should be introduced to the regimen with emphasis on play and recreation. As soon as he develops skill in a given sport he should engage in competitive games. The companion should play the game as fast as the patient's physical condition and ability permit. If the patient favors the right arm the companion as in the case of badminton, should direct the play toward that extremity without making this apparent and also avoiding pressure of this type if the patient is angered. The periods of activity should be short at first, later increased, with rest taken at the first sign of fatigue or physical complaint. The patient should not be coerced into activity. The companion should accept the patient's complaints at their face value.

The patient should be forewarned of the usual exercise muscle soreness concerning which he will usually make an 'ado'. The exercise therapy on the stationary bicycle, rowing machine and pulleys are added later. The patient will not accept these as readily as those involving the pleasure of the game. To him these are tests.

The companion should intelligently present these activities as muscle training exercises beginning with muscles not involved in the patient's complaints. Swimming will be found to be a favorite sport. Massage or heat therapy may follow the workouts to advantage and early in the treatment rest in bed. The evenings should be devoted to supervised amusement and entertainment.

The physician should see the patient at his office for psychotherapeutic interviews, the purpose of which is to encourage the patient through friendly understanding and if possible psychologic understanding, to engage in more and more activities. As the patient begins to enjoy the regimen and notes the general increase of body health, he will cooperate to the point of recovery. About six weeks is the average duration of treatment necessary to rehabilitate the patient. Some patients will use the gymnasium as a scene for indicating the alleged grave nature of their disability. These patients may be refractory to this therapy or require a much longer time to treat.

It is my recommendation that private capital or the government equip a large gymnasium for competitive sports, swimming, occupational and physical therapy, staffed by psychiatrically trained physical directors and occupational and physical therapists.

The problem of rehabilitation is a psychiatric one. Just as Freud acquired an understanding of human behavior through the study of the psychoneurotic patient, a study of psychologically protracted convalescence offers a contribution to the understanding of the total problem of rehabilitation.

DISCUSSION

DR PERRY ROGERS, Chicago. Stopping of compensation sometimes serves as good treatment for a neurosis. It requires nice judgment to anticipate which patient it will make better and which patient it will make worse. The industrial doctor has an additional hurdle to get over before he can establish a satisfactory relationship with a patient arbitrarily sent him by an employer. The doctor can surmount this primary obstacle only by an additional amount of sympathy, by a more thorough examination and by more careful attention to all details of treatment than the workman has been accustomed to expect from the doctor of his own choice. It does not take a physician trained in psychiatry to spot the patient who needs this special kind of rehabilitation. The actual management of the treatment, the prescription and the supervision of the treatment require the most skilled psychiatrist, but the skill to select the proper patient may be developed by any doctor or nurse or claim adjuster or even by an inquirer. Dr Solomon's plan of treatment works. I have had him cure a sufficient number of my

patients most of them compensation claimants, to know that he is not fooling and to know that money spent on such treatment is saved many times in disability awards. Something new has been added in the field of analytic psychiatry. The modern psychiatrist can put his finger on the source of the disability in one or two consultations, with perhaps some further study as treatment proceeds. Under the direction of such a psychiatrist this type of rehabilitation can be effected outside of hospitals and with the assistance of technicians at relatively little cost.

DR. B. B. REEVE, Chicago: What would you recommend with employees who have these tendencies? Is there anything you can do toward preventing further trouble?

DR. ALFRED P. SOLOMON, Chicago: Lump sum settlement is a form of psychotherapy. Patients do return to work when we settle their claims. In industrial practice psychoanalysis promotes the understanding by the patient of the reasons for his behavior. The physician must not react to the patient's hostility with anger, with contempt or with irritation. The doctor must recognize that the patient's behavior, including his symptoms, is a protest against something, and he must try to discover what that is and help the patient understand it. The doctor equipped with this understanding both of himself and of his relationship to the patient and the patient himself is ready to use such therapies as I have recommended, which include giving attention, interest, sympathy, understanding, exercise and recreative programs. The patient who is maladjusted at work because of grievances following an accident has to be handled individually. Hostility directed toward the employer is present in our social system and manifests itself in many other ways than in behavior after an accident.

MR. THOMAS N. BARTLETT, Baltimore: Have you been able to determine how length of treatment may be affected by the injury received?

DR. SOLOMON: Often the most protracted convalescence follows a minor injury. If a person has a severe injury his gratification over the fact that he has recovered goes a long way, particularly when he has been given the necessary amount of adequate attention, toward rehabilitation. Whether it is possible to determine by a psychiatric interview how long it will take for the patient to return to work depends on several factors. It depends on the personality of the individual and whether the structure of his personality is such that he is a rehabilitable individual. Many of these patients are simply looking for justification of their behavior or for interest or consideration. If that is given to them they do very well. There are others whose emotional problems are so grave that the prognosis is not so good and, of course, this whole question is determined by psychiatric experience. Every physician is able to do this if he will begin early and approach all patients in this manner.

MR. BARTLETT: What is the average period for recovery or is that too flexible?

DR. SOLOMON: From six weeks to two months or three months has been adequate for the average case. Industrial people are not yet ready to spend a great deal of money or time on these cases.

DR. DAVID NEILL INGRAM, Houston, Pa.: Do you ignore entirely the constitutional adequacy of the patient whom you have to treat or do you take that into consideration too?

DR. SOLOMON: Many patients of the type I am talking about come to us with a syndrome which could be classified psychiatrically as neurasthenia. The symptoms are fatigability, exacerbation of their complaints when they do work or even think of going to work, and because they are dependent individuals they tend to get weaker because they don't work. Individuals do differ in body build and endocrine makeup. I don't believe that the diagnosis of neurasthenia is a constitutional characteristic of an individual who does hard work.

Physical and Occupational Therapy in Rehabilitation

DR. JOHN S. COULTER, Chicago: Rehabilitation is the planned attempt through the use of all recognized measures under skilled direction, to restore those persons who because of disabilities do not assume to the greatest possible extent and at the earliest

possible time that place in the productive stream of society which they are potentially capable of assuming. This is the definition of rehabilitation that was approved by the Council of Rehabilitation which met in New York in 1942. This council meeting was attended by representatives from practically all the societies concerned in rehabilitation.

In the present war the Surgeon General of the Army has left the physical therapy of the injured soldier in charge of a female physical therapy aide. This work is ostensibly supervised by a board of regular army medical officers of the highest type but who have not had recent experience in physical and occupational therapy or in rehabilitation. A recent bill passed by the House of Representatives and the Senate and signed by the President gave to physical therapy aides in the army the same relative rank as nurses but omitted occupational therapy aides. Apparently there is nothing in the set up for a qualified medical officer to be in charge of rehabilitation.

Rehabilitation should start at the bedside of the injured patient and should include physical therapy, occupational therapy and later vocational rehabilitation. The injured patient who has received surgical treatment should be given physical and occupational therapy at the bedside. As soon as possible he should be sent to the department of physical therapy and to the curative workshop of the occupational therapy department. Rehabilitation of the patient starts at the bedside.

The yardstick for the evolution of surgical care should be the rehabilitation of the injured person, i.e., his restoration to the greatest possible extent and at the earliest possible time to that place in the productive stream of society which he is potentially capable of assuming.

The Manual of Physical Therapy originally published in *War Medicine* is now available as an American Medical Association pamphlet, price 25 cents. It was edited by the Council on Physical Therapy of the American Medical Association and the National Research Council. The Manual of Occupational Therapy soon to be published in *War Medicine* will likewise be published as a small pamphlet by the American Medical Association. It was written by a committee of the American Occupational Therapy Association and edited by the National Research Council and the Council on Physical Therapy of the American Medical Association. Physical and occupational therapy are the first two steps in a rehabilitation program of the injured or sick person. The manuals discuss the use of physical and occupational therapy in strains, sprains, muscle injuries, dislocations, fractures, peripheral nerve injuries, head injuries, arthritis, infantile paralysis, heart conditions, tuberculosis, spastic paralysis and nervous and mental conditions.

The Council on Physical Therapy, aided by a committee of prominent surgeons and the American Association of Limb Manufacturers, recently published "A Manual of Amputations." Here again the value of physical and occupational therapy in amputations is shown.

The Council on Physical Therapy will shortly publish the fourth edition of the "Handbook of Physical Therapy." This handbook emphasizes the place of physical therapy in the rehabilitation of the sick and the injured. It is used as a textbook in many schools for physical therapy technicians and in many medical schools.

The Council on Physical Therapy can supply mimeographed designs to make apparatus for electrotherapy and for exercises. The Council also publishes yearly a free pamphlet "Apparatus Accepted" which lists the apparatus which is safe and effective. Apparatus is not the important element in physical and occupational therapy in rehabilitation. Personnel is.

No program of rehabilitation either in our armed forces or in civilian life will be effective unless it is directed by a physician. He must be solely interested in the rehabilitation of the patient and not in furnishing to the insurance companies or courts reports on the patient's condition. The physician in charge of rehabilitation is in a most favorable position to study the human organism in its entirety, both as a living mechanism and as the essential element of human society. He and his technicians have time to discover and to help control the social influences detrimental to the sick and to the injured.

The Army is placing physical therapy physicians in charge of physical therapy departments but there is no provision for him to be in charge of rehabilitation. Few occupational curative workshops have been established. Physical and occupational therapy aides in the Army should meet the requirements set up by the American Registry of Physical Therapy Technicians at 30 North Michigan Avenue, Chicago, and the Registry of Occupational Therapy Technicians at 175 Fifth Avenue, New York. No rehabilitation program can be successful without the hands and brains of a good technician or aide.

DISCUSSION

DR JAMES H. BIRAM, Hartford, Conn. We return to work the next day 75 per cent of all patients with Colles' fractures and over 50 per cent of patients with Pott's fractures. We return to work on the same day, within an hour, 75 per cent of all of our patients with severed extensor tendons and the next day practically all of our patients with severed flexor tendons. The majority of our injured employees go back to work and work cheerfully and painlessly and have minimum disability as the result of physical therapy and occupational therapy.

DR HUSSEY. We have in Baltimore two curative workshops and physical therapy departments, one in the Johns Hopkins Hospital and one in the University Hospital, but we cannot get industrial injuries to those places for treatment.

DR D. J. GALBRAITH, Toronto. Rehabilitation starts immediately after the accident. In all serious accidents we attempt to have our rehabilitation officers get in touch with the patient as quickly as possible. Their interest and contact is maintained until the patient is back at work or has been retrained, reeducated and compensated for his remaining disability. We have perhaps a little advantage in that we can put the men back on a wage loss basis. We induce the employer to pay them their full wages, tell them how well they are doing their jobs, and we pay the employer the difference between what they earn and what their regular wages are. Early contact on the part of our rehabilitation officers does tend to prevent the development of a psychosis. Start early before the claimant begins to wonder how he is going to support his wife and family. We have set up a physical and occupational therapy division, treating about 150 patients along the lines Dr Coulter has indicated. We lack continuous control of the patients. We have to put them in boarding houses and so lose control from 5 o'clock at night until 8 o'clock the next morning, and that is a very important time in the handling of these cases. Many of them are not accustomed to the city. They find many ways of spending the time that are not beneficial to their health.

DR HUSSEY. I am impressed in Baltimore with a considerable amount of competition between the occupational therapists and the physical therapists. Is that something peculiar to our geographic location or is that something that one encounters generally?

DR JOHN S. COULTER, Chicago. In Chicago we have physical therapy and occupational therapy under the same doctor and we don't have competition. The Council on Physical Therapy thinks of occupational therapy as a part of physical therapy.

The Future of Rehabilitation

MR TERRA C. FOSTER, Washington, D. C. Few people are aware of the size of the problem of rehabilitation and its social and economic implications. There are in this country eight million people who have physical disability of such nature and degree as to cause them difficulty either in getting a job or in holding a job. Six million of them are normally in employment but two million for one reason or another are unemployed. Many drop permanently out of the labor market, but the pool is kept at a fairly constant level from a number of sources: (1) those currently disabled in industry, automobiles, home, other accidents, and from disease and congenital causes, (2) young disabled persons who reach employable age, and (3) those disabled as a result of military operations. The annual increment from these sources is now at the rate of well over a million persons a year. Thus the minimum job of a rehabilitation service

in this country is the rehabilitation of one million persons, to say nothing of another million from among the six million who are normally employed but who drop out for one reason or another. These two million persons not only are not producing, they are consuming approximately one billion dollars a year of the productive effort of others.

The vast majority of people in this country earn their living through work. The ability of a person to work and to get a job represents the economic foundation of his life. Any condition which affects the economic foundation of two million people affects the economic welfare of the nation. In the present manpower situation it is sheer folly not to make them employable and put them to work as quickly as possible.

The program which is now being considered by Congress would provide for those disabled in the military and naval services as well as for civilians. It would provide any service necessary to get a person into a job and keep him there. It would be a comprehensive program, and it would be one strong enough to meet present and future needs. But there are two obstacles which must be removed if any rehabilitation program, present or future, is fully to fulfill its potentialities as a social instrument. The first obstacle is attitude.

In the past, most employers have had the idea that a disabled worker is less efficient and more prone to accident than the physically normal and have taken on the handicapped only when the physically normal were unavailable. They have failed to realize that a disabled worker who is properly matched with a job is a safer risk than a physically normal worker improperly matched with a job. They have used physical examinations for the exclusion of the physically imperfect rather than as one of the measures for the proper placement of workers. The present manpower shortage is compelling the employment of the handicapped, but the idea of using physical examinations, tests of aptitude and personality inventories as a guide to putting the right man in the right job has not taken hold. Not only is there the inefficient use of labor but also large numbers of urgently needed workers in our war production industries are being injured and crippled.

If employers would accept the principle of proper matching of workers and jobs there could be no valid reason for the exclusion of handicapped workers. A properly placed handicapped worker is not handicapped in performing a job that is suitable to his physical condition, aptitudes and temperament. Obviously there are large numbers of the handicapped who are physically unfit and should not be accepted for employment. However, most of them can be made fit through proper rehabilitative procedures. That is the job of the rehabilitation service. Industrial surgeons should use their influence with management to establish a more scientific method of placing workers in industrial plants and a more receptive attitude toward the employment of the handicapped.

The second obstacle is the inequitable provisions of second injury clauses in workmen's compensation laws in most of the states. With few exceptions the alleged workmen's compensation laws in this country are nothing more than employer liability laws. Some of them, while quite liberal to employers and insurance carriers, are positively vicious in their effects on those injured in industry and on the other taxpayers in the community. The medical benefits are farcically small, the disability benefits are insufficient and, worst of all, the second injury clauses serve as effective barriers to reemployment.

In several states a handicapped worker has the choice of signing a waiver to his right to compensation in the event of a second injury or of not getting a job. In other states where employers might be willing to hire handicapped workers they cannot afford to do so because under the compensation laws they would be liable for the total results of a second injury, the cost of which in the event of permanent total disability would run into big money.

Do you see what these things mean to the injured worker and to the other taxpayers? First, when the medical benefits are small, the injured worker is obliged to expend a considerable part of his compensation benefits on medical care. When the remainder is gone his family or the taxpayers of his community

must take care of him because the second injury clause in his state workmen's compensation law establishes an effective barrier to his reemployment. Furthermore, in some states even where medical and compensation benefits are more nearly adequate there is neither encouragement nor incentive for the injured worker to accept the opportunity of rehabilitating himself—nor is there any penalty for failing to do so. The result is that many beneficiaries of workmen's compensation are simply pauperized.

My denunciation of the effects of these laws should not be interpreted as advocacy of their repeal. It is not. My plea is that they serve the purpose for which they were originally conceived—and I assure you that they were not conceived simply as a device for limiting the liability of the employer or insurance carrier. They were conceived for the conservation of the worker and as a means of distributing equitably the financial burden of industrial accident and disease.

The inequitable provisions of some of these laws in a number of states are seriously interfering with the recruitment of labor in war production plants. The legislatures of most of the states are now or will be in session during the next few months. May I urge that you interest yourselves and the employers with whom you may be associated in amending these laws in such a way that they will serve the purpose for which they were conceived. Let's make them real compensation laws, laws which not only will protect the employer and compensate the disabled worker but will encourage and give incentive to the injured worker to accept the opportunity to rehabilitate himself. If this is done it will contribute now to the war effort and it will greatly facilitate the rehabilitation of the thousands who are being injured in the war—a hundred thousand for each year of our participation.

Two years ago I made a proposal that the medical profession, the workmen's compensation agencies and rehabilitation officials appoint committees to get together and decide on a program in respect to the problems in which we have a common interest. I still think that it would be a good idea.

DISCUSSION

DR. HUSSEY: At one of the meetings of the International Association of Accident Boards and Commissions Mr. Foster presented a paper in which he summarized states in which the industrial accident commissions were cooperating with the vocational rehabilitation bureaus and those which were not. The ones that were cooperating in any effective manner were extremely few. My unfavorable remarks about Maryland a moment ago with reference to the use of the curative workshop clinics in physical therapy is just reversed about the vocational rehabilitation. We have in Maryland, in the industrial commission, a full time representative of the state vocational rehabilitation bureau. He reviews all the claims that come in, and he is able to follow these individuals from the very beginning. That is the type of work that the industrial commissions will have to do if we are going to have success in this program as far as industry is concerned.

MR. EDWARD I. FRIEDMAN: Providence, R. I. Prior to leaving Rhode Island to come here I was instructed by my director to promulgate two drafts of legislation to carry out some of the suggestions which have been made at this meeting. When I get back I shall have to draft a bill to set up a curative center fund and also a second injury fund. I have been vitally interested in these two particular propositions as an administrator. It has been one of the greatest problems that we have to deal with, particularly low back cases, head injury cases and maladjustment cases. Dr. Galbraith is too modest. He has a system of which he can be proud and that we should copy. When we attempt to set up this legislation, his jurisdiction is going to be our model. We are the first state in the United States to adopt a cash sickness fund, so that now when a person is unable to work by reason of unemployment, sickness or accident, in the state of Rhode Island, after April 1, 1943 we will see that he is taken care of. I hope that by the adoption of a second injury fund and a curative center fund we will further supplement the work that we have been doing.

JANUARY 13—MORNING

DR. JAMES S. MCLESTER, Birmingham, Ala., Presiding

SYMPOSIUM ON NUTRITION IN INDUSTRY

Criteria for the Evaluation of Nutrition Experience in Industry

DR. FRANKLIN C. BING, Chicago. This article appears in full in this issue, page 813.

Progress in the National Program on Nutrition in Industry

DR. ROBERT S. GOODHART, Washington, D. C. This article appears in full in this issue, page 823.

Current Nutritional Activity in Industry: A Review and Appraisal

DR. GEORGE R. COWGILL, New Haven, Conn. This article appears in full in this issue, page 817.

DISCUSSION

DR. L. B. PETT, Ottawa, Ont. The question is "What is a suitable length of time for lunch in a large industrial plant?" I am concerned with nutrition in industry in Canada, and a survey of Canadian industries shows that lunch periods vary from twenty minutes at the shortest to an hour and thirty minutes at the longest. We have recommended that not less than half an hour should be the lunch period. There are circumstances, of course, that modify this. I think the most important one that we have found in Canada depends on the size of the plant and whether the workers eat in a cafeteria, bring their lunch boxes or go home for lunch.

DR. GEORGE R. COWGILL, New Haven, Conn. I have this question: "What is the relationship of adequate food and vitamins to industrial hazards such as benzene or lead?" I am not competent to discuss the benzene poisoning problem. Regarding lead, an important factor affecting the absorption of lead is the presence of calcium in the diet. Experiments indicate that a liberal supply of calcium in the diet tends to cut down on the absorption of lead. From that point of view, a food like milk should be valuable for preventing the absorption of lead by people exposed to that metal. Here is another question: Is it true that milk has no benefit as an antidote for lead poisoning?" As a preventive measure or something that would tend to cut down on the absorption of lead, I think that milk would be regarded as having some value because of the calcium content. Another question is "When should an employee on the 3-30 p.m. to 12 o'clock midnight shift eat his meals? Should he eat a heavy meal before going to bed at, say, 1 a.m.?" I think probably some of the industrial physicians who have had actual contact with that problem would be better able to answer this question. I should say that much would depend on whether the individual plans his eating of his meals with the entire day in mind. Dr. Bristol tells me that the telephone company frequently has trouble with young women employees who want to quit because they are on some unusual shift. They say they cannot eat right, and the problem is solved by educating those people in the matter of getting an overall proper intake of food. I should think that it would be difficult to lay down any definite rule here. If a person is going to work on that shift and eats heavy meals at the end of the day, as most of us do at the end of our day, then it would be logical to eat a heavy meal around 1 a.m., but I doubt if one can set up rules that will cover all cases.

DR. L. B. PETT, Ottawa, Ont. I am going to finish the questions that I have here. "Do you believe a survey in any given industrial concern of the food habits or nutritional status of the worker is essential prior to an educational nutrition program?" And along with that is a second question that is closely allied: "Of how great value would be a survey of foods eaten by workers as reported by them over a period of a week?" I will have to confine myself to certain dogmatic statements. I do believe that a survey prior to an educational nutrition program in industry is essential. It may not be essential in the given industry concerned, provided a survey has been conducted in a representative industry, but the method of procedure that we

are adopting in Canada is that a survey has to be made in order to influence as little as possible the food habits of the people. We find that a coal miner in Alberta, for example, a western province, has not the same dietary habits as a coal miner on the east coast, in Cape Breton, Nova Scotia, and one cannot educate him in nutrition on a sound basis, on a purely theoretical basis, unless one takes into consideration his food habits. The next question I have here is "What effects do caffeine containing foods have on workers?" We have to distinguish two aspects of this question. There is the implication of the effects due to caffeine and then there are effects due to other factors, such as sugar. There are certain other considerations that have to be given this question, such as whether the caffeine containing food, let us assume it is a beverage, is a warm or a cold beverage, and what differences will be noted in each case whether it is warm or cold. I have a suspicion that effects from caffeine containing foods are for the most part not due to the caffeine they may contain. That is not to say that caffeine would not have an effect in itself, but there are certain other effects associated that may have to be considered and in general I am inclined to believe that these are deleterious. They are injurious. I particularly mention the sugar that is consumed at the same time. Under certain circumstances in a diet otherwise marginal with respect to thiamine, there is no doubt that the consumption of sugar may actually increase rather than decrease fatigue. A final question is concerned with "The excessive use of alcohol in relation to nutrition and energy needed in industry." Perhaps because I come from Canada I may point out that we are launched on a campaign right now, officially sponsored by the government but not directly associated with my department, to reduce the consumption of alcohol specifically in industrial areas.

DR. RUSSELL M. WILDER, Rochester, Minn.: Our chairman has given me a group of questions which can be answered together. One of these is "What are the objections to soda pop?" Dr. Pett has already given his objections. In connection with that subject the Council on Foods and Nutrition of the American Medical Association has recently published an article on the subject of sweets and carbonated beverages which represents the views of that council on this subject. The other questions are "What can be done to counteract the sales of nonvitamin soft drinks in my plants?" "Would it be desirable to maintain high levels of blood sugar during the day? Is there any good evidence that the taking of sugar between meals reduces fatigue?" and finally "What is the importance of an adequate breakfast and of what should it consist?" I propose answering those questions together.

There is a condition known as hypoglycemia, which is more or less the antithesis of diabetes. This low level of the blood sugar is poorly tolerated. There is a normal mechanism for maintaining a blood sugar level that does not go below 0.07 Gm per hundred cubic centimeters of blood and does not rise above 1.2 Gm per hundred cubic centimeters. When the blood sugar goes above this, as it does in diabetes, we may have some effects. If it goes higher than the threshold level of the kidney we find sugar in the urine. Moderate elevations of the blood sugar, as far as I can see, are of little harm, although the severe elevations that accompany diabetes represent something serious. Now the opposite to that, the low blood sugar, is definitely associated with weakness of the muscles and with increased irritability and, if it goes lower than that, with definite mental symptoms and finally loss of consciousness.

There is a disease that is associated with an increased supply of insulin to the body. It is represented by the development of minute tumors in the pancreas, tumors of the islands of Langerhans, producing excessive amounts of insulin, and that disease is a serious one because it is associated regularly with severe hypoglycemia. However, that disease is a relatively infrequent disease, and for every patient with that disease there are, I think, hundreds of patients who periodically have low blood sugars that are, you might say, functional in origin. There may be a nervous element to the production of some of these low blood sugars, but also that tendency to develop low blood sugars between meals is one that may be stimulated, I feel sure, by eating high carbohydrate meals. It has been shown definitely that if one gives two doses of sugar, one following the other, the

elevation of the blood sugar that is produced by the first dose is not observed in the second dose, and that the fall of the blood sugar after the dose of sugar is greater after the second dose. This hypoglycemia developing between meals is the reason that so many people I think, are turning to soft drinks and so many industrial workers are finding that feeding sugar between meals helps to tide these people along and to keep them more effective. The objection to giving sugar between meals that way is that one doesn't provide with it the vitamins that are needed for its own utilization. One throws on the rest of the day's intake of food the burden of providing those vitamins and increases the likelihood of the individual's suffering from a chronic or a mild hypovitaminosis. In some cases I think severe grades of hypovitaminosis have been produced by excessive consumption of sugar. Certainly the more of this drinking of soft drinks between meals or eating of rich carbohydrate foods such as candy bars, at those times of the day when one feels weak and empty, the more likely one is to need to continue to do so, and for that reason, as Dr. Pett said, there is some reason to think that eating sugar instead of correcting fatigue may lead ultimately to an increased sensitivity to fatigue. I agree with him in that statement.

We have found clinically at the Mayo Clinic, and others have made the same observation, that the best way to treat persons who have this tendency to low blood sugar between meals is to take them off a high carbohydrate diet and put them on a high protein, high fat diet, with rather considerable restriction of carbohydrate and particularly with restriction of sugar. They may have starches because starches are a little slower to digest. These ultimately may end up as sugar, it is true, but they enter the body less rapidly and they are associated with a less acute level of the blood sugar. They raise it less slowly than when sugar is taken as sugar and they raise it usually to a lower level, and the result is that the fall afterward is more gradual and to a less extremely low level. One of the reasons in my opinion why we are seeing more of the type of weakness in people occurring at 11 o'clock in the morning and at 4 o'clock in the afternoon and leading up to wanting something sweet to eat at those times is that the American people have gotten out of the habit of eating a good breakfast and a good lunch. The objections to eating, as so many women do and some men, a little carbohydrate in the form of fruit juice and then some jam on a piece of toast and a cup of coffee with sugar in it and letting that represent the breakfast as a whole are two. In the first place you throw sugar into the empty stomach and into the blood rapidly and you get this effect that I have described. In the second place, whenever you skimp on one meal you have to depend on the other meals to provide you with the vitamins and the other nutrients that you require for a balanced diet, and as many people not only skimp on their breakfasts but also skimp on their lunches, it throws the whole burden of taking care of the nutrition on the one evening meal, and unless you choose that meal with greater wisdom than most people possess, you are among those who are in this borderline of nutritional deficiency.

I was asked what I think a breakfast ought to contain. I think a breakfast ought to contribute its share of the various nutrients required for the day's nutrition. I think a breakfast ought to start off with a source of vitamin C and some sugar, if you wish, in the form of a fruit juice, a very satisfactory way of breaking the fast, true enough, but not a satisfactory breakfast as a whole. Then I think you ought to have your share of the B complex vitamins in that breakfast, which can best be obtained by having a satisfactory portion of a whole grain cereal, breakfast food or bread or lightly toasted bread remembering that heavy toasting destroys the vitamins in bread, lightly toasted bread or real wholewheat bread or enriched bread. With the carbohydrate that you get from the fruit juice or the tomato juice you ought to have some fat, because fat delays the emptying of the stomach and thereby prevents the sugar that you will get from those other sources from entering rapidly into the blood stream and, therefore, some butter or properly enriched oleomargarine with your toast or with your bread. Cream we could dispense with. It is a luxury food more or less. If you are not getting the butter, by all means have the cream, because it is a fat but more important than

cream is whole milk. The European habit of drinking *café au lait* is an excellent one because that is a way of consuming milk. Coffee in itself has little to be said for it as a nutrient. Then there should be some source of protein. I think that it is desirable to have an egg for breakfast, not only because of the fat but also because of the protein content, or an equivalent portion of meat is a desirable thing in the breakfast. Now then if to fill up you want to add some sugar to your coffee or some jam to your bread there is no harm in that at all, because you have the other things to take care of it and you are taking it with a meal so that it won't quickly enter the blood and produce this effect that I have talked about before. Such a breakfast will do much, I think to prevent this craving that people have for these sweet drinks between meals and will cut down the consumption of sugar between meals, particularly if such a breakfast is followed by a satisfactory lunch, a lunch which also contributes its share to the day's nutrient requirements. I think it is important that the wives of workers learn the type of breakfast they ought to serve their men.

Now there is one more question that I was asked to discuss. What can we reply to people who ask about the general distribution of vitamins in industry? I have rather felt that this question was answered in Dr. Bing's paper, in which he referred to another publication of the Council on Foods of the American Medical Association, which also can be obtained on request by writing to him, the Secretary of that Council, at the A. M. A. offices. At the present time the feeling generally among nutritionists and these advisory bodies that are dealing with these nutrition problems is that it is not wise to depend on vitamins alone to effect what we think ought to be done to the nutrition of workers, because there are other things besides vitamins that are lacking in these diets. On the other hand the subject is still open. There are certain things that are more likely to be missing in diets than others. Among them are vitamin B₁, vitamin B or riboflavin, and I imagine no serious harm would be done by adding those to the workers' diets even though you added nothing else. On the other hand, that is not the purpose of our campaign, and it also is known that one may have an adequate supply of these vitamins and have other vitamins available synthetically and still suffer from symptoms that are similar to symptoms that develop when thiamine is missing. For instance, as Dr. Sydenstricker showed not long ago, a biotin deficiency produces signs and symptoms very like those resulting from a deficiency of vitamin B₁, or a loss of thiamine, so that while it may be desirable under certain circumstances to administer vitamins generally to the workers in the plant, it is not the best way to go about the solution of the problem and it is very doubtful whether it will completely solve the problem.

DR. McLESTER: Dr. Wilder made out a case for protein because this foodstuff is absorbed more slowly and the boost we get from it is more sustained than from other foodstuffs. I would go him one better and make it two eggs at that breakfast.

DR. ROBERT S. GOODHART, Washington, D. C.: The first question that I have is "What are the criteria for judging the adequacy of a lunch for workers?" We have recommended a standard lunch, that is, a lunch that provides at least one third of the day's nutritive requirements. Those requirements that we refer to are the dietary allowances of the Food Nutrition Board of the National Research Council. That is general. Of course, I suppose what the questioner is interested in is a specific outline of how any individual physician could judge whether this diet is adequate or not. We might say that there are four foods which the inspector or the physician might look for on the lunch to see whether or not the diet is adequate. First is a meat or meat alternate, and a meat alternate includes all the varieties of meat and cheese, dried beans, soybeans and so on, the legumes. Second, two vegetables, one green or yellow. Third, milk either as a drink or as a milk dessert or milk as a soup. Fourth, the use of enriched or wholewheat bread and butter or fortified oleomargarine. A possible fifth—I make it possible—is a source of vitamin C on that diet.

We know that, according to the usual methods of the preparation of foods in mass feeding, cooked foods are not very dependable sources of vitamin C. I don't think we would be safe in relying on any cooked food as a rich source of vitamin C, therefore you would look for tomato juice, tomatoes, raw

cabbage or citrus fruit as sources of vitamin C. I made that a possible fifth item because that is one thing that most of us who take time for breakfast and can afford to do so manage to get largely in our breakfast or can get at home. However, it is unsafe for us to expect that the industrial worker will do that. We know that the great majority of workers take the inadequate breakfast that Dr. Wilder was talking about, perhaps toast and coffee, Danish pastries and coffee, or doughnuts and coffee. That is the workingman's breakfast, and if you rely on his obtaining vitamin C in that breakfast you are going to find that he will develop evidences of inadequate intake of vitamin C.

We set up a standard of one third and then we did a little figuring on our own to find out how difficult it is to meet this one third, and we found that it is a very simple matter to make up diets which meet one third of the daily requirements. In fact the meals that we made up came closer in all respects to meeting one half, and we found that it is quite easy with two meals, that is, an adequate lunch and then a light refreshment period in the mid-afternoon and mid-morning, to meet two thirds of the daily food requirements in every respect except calories and even there it is not difficult to make up the extra calories. We are most anxious that plants shall not stick to the one third idea but approach the two thirds as nearly as possible, because we know that there are many conditions—let's take again some of these big plants, ordinance plants and aircraft factories that have been placed out in fields. The people have to go 30 or 40 miles to work. They cannot get a good breakfast. Perhaps they live in trailer camps or they live in a housing development and they cannot get good meals at home. The burden of providing good meals then falls on the plant. I have talked about a good hot meal. We have been emphasizing the fact that it is possible to get cold lunches which are just as good from a nutritive standpoint as a hot meal, and very often they can be much better. Where the proper care has not been taken in the preparation of hot meals, many of your nutritive factors are lost. This does not happen in the preparation of a good cold lunch, and owing to the fact that there is a great deal of difficulty in getting good cafeteria equipment we think that the nutritive value of cold lunches should be stressed as much as possible. There is nothing wrong with the properly prepared sandwich. Two sandwiches made with enriched bread or whole wheat bread and with a proper filling and spread with fortified oleomargarine or butter, plus a glass of milk or tomato juice, make a very good lunch, providing one third of all one's daily requirements.

The second question that I have is "In rationing the amount of coffee and ice cream available to industrial cafeterias, why has the arbitrary figure of 60 per cent of last year's consumption been taken regardless of the increased number of employees? Why not reduce past consumption to a rate per thousand employees and use that as a basis for rationing?" Of course coffee is not a food, it has no food value but it may be important from the standpoint of morale. The rationing of ice cream is not fundamentally a nutrition problem. Ice cream is a good food but it is not one of the most effective ways of consuming milk. However, this question is quite pertinent, and all I can say at present is that the government is working on a plan to assure that rationing will be on a per capita basis and not on a historical basis regardless of the increased number of people in a community or in a restaurant and that problem is being worked out just as this questioner believes it should be done.

The third question is "In many plants the 'Victory Plate' or 'Special Platter' is being offered at a reduced price—the worker paying about two thirds of the price usually asked. Does your division offer specific suggestions for the contents of such platters for a weekly offering? If not, where can such data be obtained?" We have on request distributed to plants a list of menus, that is, for two weeks, for both the hot and cold lunches, and we are preparing a master menu form which can be sent to all our regional people and our state and local nutrition committees, and it will also be available to all plants. However, as Dr. Pett has pointed out, food habits vary from one section of the country to another, and we know that it is not possible for us in Washington to fix up one standard diet that will be suitable for the whole country. This is one of the main reasons for our trying to get industry to use the services of the local bodies, of the state nutrition committees and of our regional offices because these state committees make up such diets based

on the available food supplies and food habits of their localities. We should like to refer questions of that nature to the state nutrition committee in the state where the plant is located.

Another question has been referred to me and that is "Is the efficiency of vitamin C in the prophylactic treatment of heat exhaustion of sufficient value to warrant its distribution with salt in industry?" There is a lot of work going on in this subject now, and all I can say at present is that the importance of the loss of vitamin C in sweat is still very much a moot point. The evidence seems to be accumulating that perhaps not a very important amount of vitamin C is lost in the sweat. The work that has been done on the importance of vitamin C in the prevention of heat prostration was done in the chemical industries and it was done in the rooms in which the employees were exposed to trinitrotoluene. The beneficial effects observed there may not have been due to the fact that these patients lost vitamin C in the sweat but to the fact that the increased temperature in these rooms brought about an increased vaporization of trinitrotoluene and an increased absorption of trinitrotoluene, so that the vitamin C acted as an effective agent in detoxifying trinitrotoluene. This problem has to be worked out in an industry where the individuals are not exposed to the effects of such chemical poisoning.

We know that vitamin C has two actions, one a physiologic one as a vitamin and the other that it has an action demonstrated repeatedly in experimental animals in detoxifying certain chemicals. This is a pharmacologic action and apparently is not related to its physiologic one as a vitamin.

If I may ask a question myself, I should like to ask Dr. Pett to discuss some observations he has made on the relation of the consumption of soft drinks in a plant to the consumption of milk.

DR L. D. BRISTOL, New York: I have been asked "Is it advantageous to have midshift rest periods with access to food?" The answer in general I think is "yes" and there are various examples in which industries are doing this. Some industries prefer to make available at their own expense midshift feedings, whereas other industries such as the Bell Telephone Company, in most of its larger locations, at any rate, have cafeterias open all through the day when employees may obtain foods at their own expense. I think we should keep in mind also that the lack of food often gives rise to fatigue, and fatigue isn't entirely a matter of work. It is partly a matter of hunger, and we believe that a certain portion of accidents may be prevented by keeping in mind the importance of this possibility of midshift rest periods with access to food.

Second, "How can we encourage employees to drink more milk?" and "Is there any such thing as drinking too much milk in a day?" and "Are chocolate milks a desirable food?" First of all I would say that it is largely a matter of education of the employees as to the value of milk, the fact that, after all, it is of all the foods perhaps the ideal food, and then see that it is made available at as low a cost as is consistent with the budget of the industry. If you can have milk available at a low figure as compared with some of the other drinks, you will have more milk consumed without any doubt. Then too I think we must educate our employees, particularly the women, that milk isn't necessarily fattening. For some reason or other no woman likes to drink much milk because she thinks it is going to make her fat, and our reply there is "Good nutrition means fitness and not fatness and that includes the use of milk." So far as drinking too much milk in a day is concerned, I would say there isn't very much danger along that line. The danger is altogether in the other direction.

"Is chocolate milk a desirable food?" Well, certain chocolate milks are better than most of the other soft drinks. The only difficulty is that most of these chocolate shakes and so on are frequently made with skimmed milk and you don't get the nutritive value and they have that additional sweet that Dr. Wilder has referred to.

Third, "Where can one obtain suitable advice about diet?" Well, first of all I should certainly say from your doctor. Don't forget your doctor in this whole program. He is trained, or should be trained, and perhaps he will refresh his training if he needs to do so to answer some of these questions. Secondly, I would say your doctor's organization, and that means largely the Council on Foods and Nutrition, where there is a vast amount

of information with reference to diet. Then briefly, other groups such as the local health department, the local medical society, local and state nutrition committees that have been mentioned, the agricultural colleges and universities, and at the federal level the agencies that have been referred to by Dr. Goodhart.

The next question is "If we have not up to this time laid such a basic understanding of diet and nutrition which will carry us through the present emergency, can we expect to accomplish results now in the relatively short time available commensurate with the use of manpower required for the effort?" I should say that by all means every effort we can put into this will pay returns in the war effort, but beyond that it seems to me we are laying a basis for nutrition education in this country that is going on through the period after the war. If World War I laid the basis for the venereal disease education and control, I am one who believes that World War II in the field of health will lay the basis for nutrition education and emphasis all through the coming years.

Then finally, this question that Dr. Cowgill referred to with reference to the relationship of meals to shifts. I think I cannot do better than just refer to our instructors' handbook that is used in connection with our nutrition course for employees.

DR HELEN S. MITCHELL, Washington, D. C.: One point that has not been brought up is the employees in the small plant of twenty to thirty or even fifty where inplant feeding is impossible and where they do have a third shift or work overtime if they have war orders today. That has come to my attention several times, particularly in Detroit, where there is a very large population of these small plants and where some of the employers have thought that something should be done toward offering that afternoon lift at 4 o'clock, for instance, when they bring their lunches and eat them at 12, work through to 8 or 10 at night and there is no stop between 12 and 8 for anything and there is no inplant feeding. They bring their lunches or eat out. The effort there has been thwarted in several cases by the fear of patronage, so again we are met with thwarted good intentions on the part of employers recognizing the need for doing something, and particularly in plants employing older workers, because a good many of these small plants have workers who have been with them twenty, thirty or forty years and they don't lay them off today when they are busy. They are keeping them on, but they are very fearful of their standing the gaff of a ten or eleven hour day, which is what is happening, and yet there is no adequate provision or effort or interest on the part of the employees collectively toward providing that ten minute period or even accepting it if the employer wishes to offer it. It creates a problem.

DR PETT: Dr. Goodhart's question concerned the problem of milk in relation to soft drinks in industrial plants, and since he has directed it to me I assume that it asks for our experience in Canada, because we have had some experience in decreasing the use of soft drinks in an industrial plant by various methods. The first method I shall mention had nothing to do with my office. The government put a tax on soft drinks of 1 cent a bottle. We observed the effects of that immediately, and I should like to add one interesting comment. Not only did milk sales jump considerably but this increase has been sustained for about seven months now. That is quite important. It wasn't a temporary change. However, there are some other methods that have been used in Canada with success. A second method is that the plant management—and this has been especially possible in a new plant—simply orders a limit of perhaps two bottles of soft drinks a day per employee. This may sound rather autocratic but it has been done and, indeed, we have plants in Canada where the average consumption has been as high as ten bottles a day and the plant management ordered it reduced to two bottles a day, a definite ration within the plant, and immediately the milk consumption increased enormously, and the interesting point is that in those plants at the present time the consumption of soft drinks is actually less than two bottles per employee daily. It is reduced below the ration set by the plant. This means that milk can hold its own once the habit is started. The third fact I should like to mention is that when access to a bottle of milk is made easy, that is, when it is easy to get, we have found that milk will more than hold its own in popularity as a beverage both between meals and at meals with soft drinks.

DOCTORS AT WAR

Radio broadcasts of Doctors at War by the American Medical Association in cooperation with the National Broadcasting Company and the Medical Departments of the United States Army and the United States Navy are on the air each Saturday at 5 p. m. Eastern War Time (4 p. m. Central War Time, 3 p. m. Mountain War Time, 2 p. m. Pacific War Time). An exception is the Chicago area, where the broadcasts are heard by transcription at 8 p. m. Central War Time Saturdays on Station WMAQ.

The titles and speakers for the next four programs are as follows:

March 13 When To Call Your Doctor
March 20 Fit to Fight
Guest speaker: Major General Henry S. Aurand, Commanding General Sixth Service Command
March 27 War Worker Sleeps Here
April 3 The White Plague 1943
Guest speaker: Dr. Kendall Emerson, Managing Director, National Tuberculosis Association

April 10 Battle Stations at Home
Guest speaker: Col. George Buehr, Chief Medical Officer, Office of Civilian Defense

BEFORE THE DOCTOR COMES

Beginning Thursday, March 4, the American Medical Association program on WLS entitled 'Before the Doctor Comes' will no longer be a part of the Homemakers' Hour but will be a separate program. It can be heard on Radio Station WLS (890 kilocycles) at 9:45 a. m. every Thursday up to and including May 27. Mrs. Harriet H. Hester will interview Dr. W. W. Bauer, Director of the Bureau of Health Education, or Dr. Austin C. Smith, Secretary of the Council on Pharmacy and Chemistry, on common home health problems. The titles of the next three programs are as follows:

March 18 The Child with Headache
(Bauer)
March 25 The Child with Tummy Ache
(Bauer)
April 1 The Child with Ear Ache
(Bauer)

MEDICAL LEGISLATION

MEDICAL BILLS IN CONGRESS

Changes in Status—H. R. 812 has been favorably reported to the House providing for the issuance of documentary evidence of United States citizenship. There are many native born Americans who are unable to present evidence of citizenship because of the fact that at the time of their birth laws were not in effect providing for the registration of births. The reported bill provides a method by which such persons may obtain a certificate of citizenship. The House Committee on Military Affairs has begun hearings on H. R. 997, a bill proposing to amend the National Defense Act by eliminating the Medical Administrative Corps in the Medical Department of the Regular Army and substituting therefor a pharmacy corps. H. R. 1749 has passed the House extending the existing medical, hospital, domiciliary and burial benefits available to veterans of World War I to veterans of World War II. H. R. 1936 has been reported to the House, authorizing an appropriation of \$2,000,000 for expansion of naval facilities for hospitalization of dependents of Navy and Marine Corps personnel, to provide the types of hospital service which shall be available to such dependents, to include dependents of Coast Guard personnel while the Coast Guard is operating as a part of the Navy, and to authorize hospital service outside the continental United States and in Alaska to certain persons not in the naval service. S. 739 has passed the Senate and House providing that during the present war and for six months thereafter personnel of all components of the Army of the United States may be detailed as students at technical, professional and other educational institutions, or as students, observers or investigators at industrial plants, hospitals and other places. S. 786 has been passed by the Senate, providing for the rehabilitation of veterans disabled in the present war.

Bills Introduced—H. R. 2017, introduced by Representative Angell, Oregon, provides for the payment of annuities to blind persons. The annuity payable to a blind person, the bill provides, will be paid in monthly instalments which are mathematically sufficient, when added to any other income of such person, to provide him with an average monthly income of \$100, except that no such instalment will be for an amount in excess of \$50. The term 'blind person' is defined by the bill to mean a person who is 21 years of age or over, a citizen of and resident within the United States including its territories and possessions, and who has not more than 20/200 of visual acuity in the better eye with maximum correction or whose field of vision is limited to 20 degrees or less from the fixation point in all quadrants. H. R. 2041 introduced by Representative Keefe, Wisconsin, would authorize appropriations to the Children's Bureau for payments to states for medical, nursing and hospital, maternity and infant care for wives and infants of enlisted men in the armed forces of the United States of the fourth, fifth, sixth and seventh grades. The sum

of \$1,200,000 would be authorized for the fiscal year ending June 30, 1943 and for each fiscal year thereafter during the period of the present war and for six months following its termination but not in excess of a total of \$6,000,000. H. Res. 146 introduced by Representative O'Connor, Montana, contemplates the creation of a special committee of the House of Representatives composed of five members to be appointed by the Speaker to (1) investigate the hospital problem throughout the United States in order to determine the hospital beds available for marines, soldiers, sailors, coast guards, men, members of the merchant marine and any or all persons engaged in warfare, (2) investigate the use of existing civilian hospital facilities, (3) study the hospital problem in the United States as a whole as affecting not only war industries but industries in general throughout the United States and (4) report in writing to the Congress the results of such investigations together with its recommendations. H. R. 1824, introduced by request by Representative Lesinski, Michigan, would direct the Administrator of Veterans Affairs to promulgate regulations pertaining to service connection containing additional provisions requiring that as to those veterans who are shown to have been engaged in combat with an enemy of the United States during the present war or who are shown to have been subjected to other arduous conditions of active military or naval service of extraordinary character, any subsequent disability resulting from an injury or disease which could have resulted by way of incurrence or aggravation traceable to such veteran's active military or naval service shall be adjudicated as directly due or aggravated by such service in line of duty. H. R. 1858 introduced by Representative Lane, Massachusetts, provides that in the administration of any laws and veterans regulations conferring rights, privileges or benefits on persons who served in the military or naval forces of the United States during the World War, their widows, children and dependent relatives, those persons who served as members of the United States Merchant Marine during the period of the World War and who have been honorably separated from such service shall be held and considered to be veterans of such war.

STATE MEDICAL LEGISLATION

Arizona

Bill Passed—H. 146 passed the house, March 1. It proposes to require every physician attending a pregnant woman to take a sample of her blood not less than ten days after the first visit and to submit such sample to an approved laboratory for a standard test for syphilis.

Arkansas

Bill Introduced—S. 300, to amend the public welfare law, proposes to eliminate medical care and treatment for indigents. Only hospitalization would be furnished.

Bill Passed—H 432 passed the house, February 25 It proposes to prohibit the sale of appliances, drugs or medicinal preparations having special utility for the prevention of conception or venereal diseases without a license issued by the state board of pharmacy but excepts physicians and medical practitioners regularly licensed to practice medicine or osteopathy from the provisions of the proposal

California

Bill Introduced—A 1627, to amend the Business and Professions Code, proposes to authorize the renewal of professional licenses of persons who have served in the armed forces, if they possessed a current, valid and unrevoked license at the time of entry into such service and if they apply for renewal within sixty days after the termination of such service

Bill Passed—A J R 26 passed the assembly on January 29 and the senate on January 30 It requests Congress to enact S 216 or H R 997, either of which would create a pharmacy corps in the United States Army

Colorado

Bill Passed—H 525 passed the house on February 23 and the senate on March 3 It proposes to authorize the state board of medical examiners to grant and revoke license to practice chiropody, defined as the diagnosis and medical, surgical, mechanical, manipulative and electrical treatment of ailments of the human foot and leg, excepting amputation of the foot or leg or the administration of an anesthetic other than local or the reduction of dislocations or fractures Surgical treatment is further defined to mean the surgical treatment of all minor foot or leg ailments excepting surgery on the bony structure or ligamentous tissues of the foot or leg

Connecticut

Bill Introduced—Substitute for S 261, to amend the premarital examination law, proposes to allow the required certificate to be signed by a physician licensed to practice medicine or osteopathy in Connecticut or in any other state or territory of the United States or the District of Columbia

Bill Passed—S 261 passed the senate, February 25 To amend the premarital examination law, it proposes to permit the required certificate to be signed by a physician licensed to practice medicine in the state of Connecticut or any state or territory of the United States or the District of Columbia

Delaware

Bill Passed—S 49 passed the senate, March 1 It proposes to require all school children to be immunized against smallpox and diphtheria unless excused by a written statement by a reputable physician

Georgia

Bills Introduced—S 188 and H 552 propose the abolition of the State Boards of Medical Examiners, Chiropractic Examiners and Osteopathic Examiners and to create in their stead a State Commission of Medical Examiners, Georgia Commission of Chiropractic Examiners and State Commission of Osteopathic Examiners of Georgia The powers, duties and qualifications would be the same except that members appointed by the governor must be approved by the secretary of state and confirmed by the senate H 336 proposes that the unlicensed practice of chiropractic, medicine and osteopathy shall be a public nuisance which may be abated by use of the injunctive process The burden would be on the person charged to show that he has a validly issued license H 442 proposes to require every practicing physician to publish quarterly, in a newspaper of general circulation in the county wherein he practices, a list of the names and addresses of any patients who died during the preceding quarter while under his care and a statement of the cause of such death H 566 proposes to require all persons desiring to be married to present a certificate from a medical doctor showing freedom from venereal diseases of all kinds

Idaho

Bill Introduced—S 140, to amend the occupational disease act, proposes to authorize the industrial board to summon the medical panel to attend hearings and authorizes the members of such panel to question witnesses

Illinois

Bill Introduced—S 83 to amend the law relating to narcotic drugs, proposes to exempt therefrom the prescribing of certain attenuated narcotic preparations

Indiana

Bills Introduced—S J Res 7 proposes the adoption of a joint resolution memorializing Congress to pass legislation establishing a pharmacy corps in the army H 370 proposes regulations for the admission of patients to county tuberculosis hospitals

Bills Passed—S C R 14 passed the senate February 22 It proposes a resolution requesting Congress to enact necessary legislation to make available federal funds, after the war, for assistance to the several states in providing necessary and needed hospital facilities in industrial centers S 135 passed the house March 3 It proposes to prohibit school authorities from employing food handlers who are addicted to drugs or who have tuberculosis or syphilis in an infectious stage and to require all school employees to undergo a physical examination for tuberculosis at least once every three years by a duly licensed doctor of medicine H 413 passed the house February 22 It proposes that every person employed in a place serving food shall secure a certificate from the health officer showing freedom from contagious, infectious and communicable diseases and limits the health officer to a fee of \$2 for such certificate and examination

Iowa

Bill Introduced—H 407 proposes to require attending physicians to notify the department of public safety of the birth of any child and to require the department, or the hospital in which the child is born, immediately to take or cause to be taken footprints of such child

Kansas

Bill Passed—H 332 passed the house, March 3 It proposes to require every physician to take or cause to be taken a sample of blood of any woman whom he diagnoses as being pregnant such sample to be taken within fourteen days after the diagnosis is made

Maine

Bill Introduced—H 1211 proposes the enactment of a cash sickness compensation act

Maryland

Bill Passed—H 53 passed the house, February 24 It proposes to amend the insurance code by exempting from the provisions thereof any policy or contract granting solely and exclusively hospitalization insurance The present law exempts any policy or contract issued by a nonprofit association

Bill Enacted—S 84 has become chapter 59 of the Laws of 1943 It amends the medical practice act by eliminating the proviso that no two courses of medical lectures shall be either begun or completed within the same calendar year This amendment is for the purpose of enabling graduates of accelerated medical courses to obtain licensure in Maryland

Massachusetts

Bill Introduced—S 357 proposes to require the department of public health to provide for the care and treatment of dipsomaniacs and inebriates

Bill Enacted—H 1013 has become chapter 41 of the Laws of 1943 It provides that physicians shall report all cases of wounds from a BB gun to the commissioner of public safety and to the police authorities

Michigan

Bills Introduced—S 192, to amend the osteopathic law, proposes to authorize the Michigan State Board of Osteopathic Registration and Examination to modify by order the educational requirements prescribed by the present act during the present emergency H 176 proposes a revision and codification of the existing workmen's compensation law

Missouri

Bills Introduced—S 53 proposes to authorize cities of the third class acting through their city councils to levy and collect a license tax and to regulate physicians, chiropractors,

osteopaths hospitals, sanatoriums, health schools and many other businesses and occupations H 299 proposes the creation of a state board of examiners in the basic sciences to examine in the subjects of anatomy, physiology, chemistry, bacteriology and pathology any person desiring to practice any form of the healing art H 300 proposes to require a practitioner of medicine, surgery, dentistry, optometry, osteopathy, chiropractic, chiropody and veterinary surgery, when using the prefix "Doctor" or "Dr." in connection with his name, to affix thereto suitable words clearly designating the degree held by such practitioner or the particular type of practice in which such person is engaged H 319 proposes the creation of a state board of naturopathic registration and examination and defines naturopathy as the method or science of treatment and prevention of human ailments through the use, method and application of such natural methods as among other agencies, physiotherapy (electro-therapy, hydrotherapy, thermotherapy, colon therapy, actino-therapy) phyto-therapy, biochemic cell salts, dietetics, food concentrates, accessory food substances, hygiene, sanitation, first aid, clinical laboratory procedures, diagnosis, x-ray as taught in the approved schools and colleges and institutions of naturopathy provided that nothing in the proposal shall authorize any naturopath to practice materia medica, major surgery, osteopathy, chiropractic or any other of the legalized forms of the healing sciences

Montana

Bill Introduced—S 172 to amend the medical practice act proposes to increase the penalty for practicing medicine without a certificate from a fine of not more than \$1,000 or not less than \$250 or imprisonment in the county jail for not more than one year or not less than ninety days to a fine of not more than \$2,000 or less than \$500 or imprisonment in the state prison for not more than three years or not less than one year

Bill Passed—H 118 passed the senate February 26 To amend the medical practice act, it proposes to authorize the board of medical examiners to prescribe and enforce reciprocity requirements current with changes in standards of the practice of medicine and surgery

Nebraska

Bills Introduced—Legislative bill 298 to amend the motor vehicle law, proposes to define the term "while under the influence of alcoholic liquor or any drug" Legislative bill 371, to amend the motor vehicle law proposes to authorize the admission in evidence of chemical analysis of the blood, breath, urine or other bodily substance of an accused person revealing the presence in the blood of the accused of 0.05 per cent or more by weight of alcohol

Nevada

Bill Introduced—A 141 proposes to authorize the board of medical examiners to grant qualified physicians a temporary license to practice medicine, surgery or obstetrics in any particularly specified part of the state for and during the period of time limited by the license The proposal would further authorize the board of medical examiners, from time to time, to restrict, enlarge or change the territorial limits stated in such temporary license

New Jersey

Bills Introduced—S 68, to amend the compulsory vaccination law, proposes to make it mandatory instead of optional for the board of education to exclude from school any teacher or pupil who has not been vaccinated A 150 proposes to authorize the board of freeholders of any county of the second or third class to abolish the office of coroner and to create the office of chief medical examiner, such officer to be a licensed practitioner of medicine or surgery, resident in the county, of recognized ability and good standing in his community

New Mexico

Bills Introduced—H 182 proposes to repeal the basic science law enacted in 1941 H 219, to amend the law relating to school employees, proposes to prohibit the employment of teachers afflicted with syphilis and to require all school employees to present annually a certificate from a licensed physician showing freedom from any transmissible disease, which shall include tuberculosis and Wassermann tests

New York

Bills Introduced—S 851 and A 1144, to amend the workmen's compensation act, propose to authorize an injured employee to receive dental care and treatment, when necessary, and to select his own dentist to treat him S 884 proposes to prohibit scientific experiments or investigations on living dogs A 1125, to amend the medical practice act, proposes to postpone until July 1, 1944 the 1942 amendment exempting students, interns and resident physicians from the operation of the medical practice act A 1185, to amend the workmen's compensation law, proposes to authorize an injured employee to select the hospital to which he shall be sent for care and treatment

North Carolina

Bill Introduced—S 211 proposes to amend the law relating to the incorporation of nonprofit hospital service corporations so as to authorize the operation of nonprofit medical service plans as well The term 'hospital service plan' is defined as including the contracting for hospital care, laboratory facilities, x-ray facilities, drugs, appliances, anesthesia, nursing care, operating and obstetric equipment, accommodations and any other services authorized or permitted to be furnished by a hospital under the laws of North Carolina and approved by the North Carolina Hospital Association or the American Medical Association The term 'medical service plan' is defined as including the contracting for medical, obstetric, surgical and any other professional services authorized to be furnished by a duly licensed physician

Bills Passed—S 254 passed the senate, February 26 It proposes the creation of a Hospital Authority to engage in hospital construction, maintenance and operation H 429 passed the house on February 25 and the senate on February 26 It proposes that any person having tuberculosis in a communicable form who fails to follow the instructions given him by an agent of the county board of health as to precautions which he should take shall be imprisoned in the Prison Department of the North Carolina Sanatorium

North Dakota

Bills Passed—S 77 passed the senate, February 22 It proposes to provide for the establishment, maintenance and duties of a district board of health and provides that the district health officer appointed by such board shall be a physician and surgeon regularly licensed to practice medicine and surgery in the state H 229 passed the house February 23 It proposes a law for the organization and regulation of nonprofit hospital service plan corporations

Ohio

Bill Introduced—H 244, to amend the law authorizing the creation of corporations to conduct a medical service plan proposes that any physician in the armed forces shall be considered as residing and actively practicing in the county in which he resided and actively practiced at the time of his entrance into the armed forces, and proposes further that no certificate of authority or license to operate such a medical service plan shall be issued during the war emergency or within six months thereafter

Oregon

Bill Introduced—S 284 proposes to authorize the payment of compensation to employees disabled by an occupational disease

Bills Passed—H 103 passed the senate, February 26 To amend the law relating to the examination of handicapped children, it proposes to authorize examinations of the eyes of such children to be made and the findings certified to by qualified and licensed optometrists H 350 passed the Senate, February 26 It proposes to authorize commissioned medical officers of the army to execute the required certificate necessary under the state premarital examination law

Rhode Island

Bill Introduced—H 653 proposes to authorize the director of education to arrange for annual lectures to high school students on the problems of cancer and the means for its cure and control

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST SUCH AS RELATE TO SOCIETY ACTIVITIES NEW HOSPITALS EDUCATION AND PUBLIC HEALTH)

ARIZONA

Society News—The Pima County Medical Society was addressed in Tucson, January 12, by Capt Robert J Stein, M C, U S Army, on "An Open Psychiatric Division in a General Hospital", Major Sigmund Mage, M C, U S Army, "Present Status of Surgery in Treatment of Gastrointestinal Ulcer," and Lieut Col William J Kennard Jr, M C, U S Army, "Personal Experiences in Action in Eastern Front"

ARKANSAS

Norman Baker Loses Again in Court—Norman Baker former operator of alleged "cancer cure" hospitals in Arkansas and Iowa, serving a four year federal sentence on charges of using the mails to defraud, has lost a \$25,000 civil action in the Arkansas supreme court to one of his former associates, Rennie A Bellows, who died during pendency of the suit, according to the Davenport Times, March 2. Affirming a Carroll County chancery decree, the high tribunal ruled that Baker should pay this amount to the estate of Bellows to satisfy his alleged promise to give Bellows an interest in his hospital at Eureka Springs. Bellows had served as superintendent of the hospital

ILLINOIS

Society News—Dr W Kress McIntyre, St Louis discussed "Cancer of the Rectum" before the Madison County Medical Society, Granite City, February 5.—Dr Isaac A Abt, Chicago, discussed "Sulfa Drugs in the Treatment of Children" before the Livingston County Medical Society, February 18, at Pontiac. A sound film on 'Peptic Ulcer' was also shown at the meeting

Chicago

Personal—Dr Francis B Gordon has been promoted to associate professor of bacteriology at the University of Chicago School of Medicine.—Nathaniel Leverone was elected president of Goodwill Industries recently. One of the group's major projects for the coming year will be to formulate plans for training disabled soldiers

Dr du Vigneaud Addresses Chemists—At a dinner meeting of the Chicago Section of the American Chemical Society, March 18, Vincent du Vigneaud, Ph D, professor and head of the department of biochemistry, Cornell University Medical College, New York, will discuss "The Chemical Nature of Biotin". Following the dinner, group meetings will be held to discuss various subjects

Annual Alpha Kappa Kappa Banquet—The Alpha Kappa Kappa Fraternity chapters of the city held their annual tri-chapter banquet at the Chicago Athletic Club, March 12. Dr Herman L Kretschmer, treasurer of the American Medical Association, was toastmaster. The three participating chapters are Xi of Northwestern University Medical School, Nu of Chicago University School of Medicine and Eta of the University of Illinois College of Medicine. Allan Rogers of Northwestern was chairman of the tri-chapter banquet committee

Dean David J Davis to Retire—Dr David J Davis associated with University of Illinois College of Medicine for twenty-nine years will retire September 1 as professor and head of the department of pathology, bacteriology and public health and dean of the medical school. His successor has not yet been named. Dr Davis, who was born in Racine Wis in 1875, will reach the university's compulsory retirement age of 68 in August. Dr Davis graduated at Rush Medical College in 1904, taking his degree of doctor of philosophy at the University of Chicago in 1906. He became professor of pathology at Illinois in 1914 and dean in 1925

Stieglitz Memorial Lecture—Carl S Marvel Ph D professor of organic chemistry, University of Illinois Urbana Ill will deliver the third lecture under the Julius Stieglitz Memorial Lectureship on April 2 in Kent Theater, University of Chicago, on the subject "The Structure of Vinyl Polymers". The lectureship was established in 1940 under the auspices of the Chicago Section and the alumni of the chemistry depart-

ment of the University of Chicago to honor Julius Stieglitz Ph D, who at the time of his death in 1937 was professor of chemistry emeritus at the University of Chicago. Dr Stieglitz was a charter member of the Council on Pharmacy and Chemistry of the American Medical Association, serving continuously from 1905 to 1926, and chairman of its committee on rules and procedures

INDIANA

Outbreak of Smallpox—Fifty-one cases of smallpox have been reported in a recent outbreak in Lake County. 40 cases being recorded in Gary alone. No deaths were reported

Changes in Health Personnel—Dr Paul W Ferry Kokomo, has been elected president of the Kokomo Board of Health.—Dr John H Green North Vernon, was recently named secretary of the North Vernon Board of Health.—Dr Robert O Scott, Charlottesville, has been chosen coroner of Hancock County.—Dr Everett A King Hardinsburg Ky, director of the tricity health unit of Breckenridge Hancock and Meade counties, Ky, has been named full time health director for Evansville and Vanderburgh County

The Mann Lecture—The second annual Frank C Mann Lecture was delivered by Dr Warren H Cole, professor and head of the department of surgery, University of Illinois College of Medicine, Chicago, on "Advances in Gastric Surgery". Dr Andrew C Ivy, director of the Naval Medical Research Institute Bethesda, Md, who was originally scheduled to give the lecture, had to cancel his engagement. The Frank C Mann Lectureship in Applied Physiology was founded and presented to the University of Indiana School of Medicine in 1941 by the Phi Beta Pi medical fraternity. The first lecture was delivered by Dr Mann, Rochester, Minn, in whose honor the lectureship was established

IOWA

State Medical Meeting in Des Moines—The Iowa State Medical Society will hold its ninety-second annual session at the Hotel Fort Des Moines, Des Moines April 29-30, under the presidency of Dr Frank P Winkler Sibley. Out of state speakers will include Drs Harry L Smith Rochester Minn on "Coronary Disease Its Recognition and Management", Arthur W Proetz, St Louis "Practical Management of Headache" and Virgil S Counseller Rochester "Pelvic Surgery as Related to General Practice". Iowa physicians who will participate in the program will include

Dr Ralph E Gray Eldora Social and Medical Aspects of the Boys Training School at Eldora
Dr Harold E Farnsworth Storm Lake Care of the Premature Infant in General Practice
Dr Andrew W Bennett Iowa City Malaria Epidemic in Iowa
Dr Anthony C Pfohl Dubuque Surgery in Medical Emergencies
Dr Raymond J Harrington Sioux City Intrathoracic Tumors as a Diagnostic Problem
Dr James A Greene Iowa City Tropical Medicine in Iowa in the Postwar Era
Dr Paul O Nelson Emmetsburg Early Diagnosis and Treatment in Tuberculosis
Dr Elmer L De Gowan Iowa City Blood Banks in Iowa
Dr Julian D Boyd Iowa City Body Measurements in Physical Diagnosis
Dr Frank R Peterson Iowa City Management of Peptic Ulcers Requiring Surgery
Dr Burton Raymond Weston Mason City A Surgical and Clinical Contribution to Right Sided Pain
Dr Edmund S Donohue Sioux City Delayed Bone Grafts
Dr John B Synhorst Des Moines Surgery of the Colon
Dr Lewis M Overton Des Moines Use of Sulfonamides in Open Wounds (Clinical Study)
Dr John W Dulin Iowa City Use of Stainless Steel Wire as Suture Material
Dr Christian B Lugnbuhl Des Moines Acute Pulmonary Conditions Simulating Abdominal Disorders
Dr Earl C Montgomery Atlantic Intracocular Neuritis
Dr Frank Harold Reuling Waterloo Glioma of the Optic Nerve
Dr Kenneth C Swan Iowa City Abnormal Retinal Correspondence
Dr John E Rock Davenport Staphylococcal Septicemia Tonsillar in Origin
Dr Dean M Lierle Iowa City The Right to Hear

At the annual banquet Dr Walter A Sternberg Mount Pleasant will be the toastmaster. Virgil M Hancher LL D president, State University of Iowa, Iowa City, will deliver the principal address. Dr Winkler and Dr Lee R Woodward, Mason City, president-elect of the state society will also address the banquet. Groups meeting during the session of the state society include the State Society of Iowa Medical Women, Iowa Public Health Association and Iowa Anesthesiological Society. There will also be luncheons of alumni of Northwestern University Medical School Chicago, and the State University of Iowa College of Medicine Iowa City. The woman's auxiliary to the Iowa State Medical Society will hold its annual session April 29-30. The speakers will include Drs Ransom D Bernard Clarion, on "Present Trend of Medical Legislation" and Carl F Jordan Des Moines, "The State Board of Health and the Blood Donor Program"

MARYLAND

State Milk Regulations Amended—The state department of health announced the following amendment to the state milk regulations

By January 1 1945 all milk and milk products consumed raw shall be from herds or additions thereto which have been found free from Bang's disease as shown by blood serum tests for agglutinins against *Brucella abortus* made in a laboratory approved by the director of health. All such herds shall be retested at least every twelve months and all reactors removed from the herd. A certificate identifying each animal by number and signed by the laboratory making the test shall be evidence of the above test.

According to preliminary figures of 48 cases of undulant fever reported in Maryland in 1942 47 occurred in the counties and one in Baltimore City. There were no deaths.

Venereal Disease Council—Baltimore *Health News* announces the organization of a new public health-social agency known as the Baltimore Venereal Disease Council. It was appointed under the auspices of the Baltimore Mobilization Committee and aims to project a modern attack on syphilis, gonorrhea and other venereal disease as a responsibility of community agencies as a whole rather than as one unit. Three study committees have been formed, one on legislation, one on rehabilitation and one on medicine, public health and pharmacy. Efforts will be made to assist military authorities in the current venereal disease control program but the major efforts will be toward a long range plan that will improve the venereal disease record of Baltimore.

MASSACHUSETTS

Tufts Alumni Dinner—The Tufts Medical Alumni Association will hold its annual meeting and dinner on Wednesday evening March 31 at the Copley Plaza Hotel Boston. Hon. Paul V. McNutt, chairman of the War Manpower Commission, Washington, D. C. will be the guest speaker. Other speakers will be Leonard Carmichael, LL.D., president of Tufts College who will discuss "The Medical School and the War," Dr. Alonzo K. Paine, Boston, president of the association "Alumni Activities," and Dr. Frederick W. Maroney, Brooklyn College, New York. The Twenty Five Year Class.

MICHIGAN

Discussion of Neuropsychiatry in Selecting the Armed Forces—The Michigan Society of Neurology and Psychiatry is sponsoring a panel discussion on "Importance of Neuropsychiatry in the Selection of Men for the Armed Forces" at its meeting in Detroit, March 25. National and state directors of Selective Service and representatives of the armed forces will speak.

Industrial Medical and Surgical Conference—The committee on industrial health of the Michigan State Medical Society and the department of postgraduate medical education, University of Michigan, Ann Arbor, are cooperating in a postgraduate industrial medical and surgical conference to be held at the Horace H. Rackham Memorial, Detroit, April 8. Among the speakers will be:

- Dr. James G. Townsend, Bethesda, Md., "The Present Status of Medical Programs in War Industries"
- Dr. Roy D. McClure, Detroit, "Study on Minor Burns"
- Dr. Max R. Burnell, Flint, "The Employment of Women in Industry"
- J. J. Bloomfield, Bethesda, "Industrial Hygiene in the War Industries"
- Mr. Andrew T. Court, Labor Economics Section, General Motors Corporation, Detroit, "Industrial Illness and Disability Analysis"
- Dr. Herman H. Riecker, Ann Arbor, "Heart Disease in Industry"
- Dr. Louis Schwartz, Bethesda, "Dermatitis in Industry"
- Dr. Barney J. Hein, Toledo, Ohio, "Management of the More Common Industrial Fractures"
- Dr. Parker Heath, Detroit, "Traumatic Eye Injuries and Epidemic Keratoconjunctivitis"
- Dr. Carl E. Badgley, Ann Arbor, "Back Injuries—Medical Legal Complications"
- Dr. Frank F. Tallman, Lansing, "Mental and Psychological Problems Relative to Industrial Employment"
- E. P. Chester, director, bureau of rehabilitation service, state department of education, Hartford, Conn., "The Employment and the Evaluation of the Handicapped Worker in Industry"
- L. J. Carey, general counsel, Michigan Mutual Liability Insurance Company, Detroit, "Medicolegal Phases of Industrial Employment"
- John W. Gibson, chairman, Michigan Department of Labor and Industry, Lansing, "Viewpoint of the Michigan Department of Labor and Industry"
- John Lovett, general manager, Michigan Manufacturers Association, Detroit, "Viewpoint of the Employer"
- Dr. Carl M. Peterson, secretary, Council on Industrial Health, American Medical Association, Chicago, "Viewpoint of the Medical Profession"

At the banquet in the evening the speakers will be Gov. Harry F. Kelly, Lansing, and Charles F. Kötterling, Dr. Engring, vice president in charge of research, General Motors Corporation, Detroit.

MINNESOTA

Mayo Foundation Lectures—Brigadier Walter Rowley Bristow, London, chief orthopedic surgeon, Royal Army Medical Corps, gave a Mayo Foundation Lecture in Rochester, February 8, on the "Management of War Casualties in British Forces." Dr. Harrison F. Ghippin, Philadelphia, gave a similar lecture, February 5, on the "Management of Pneumonia."

Personal—Dr. Wilburn O. B. Nelson has been named health officer of Fergus Falls to succeed the late Dr. William A. Lee—F. O. Hanson, D.D., for nearly ten years superintendent of Swedish Hospital, Minneapolis, has resigned his position to become director of appeal at Gustavus Adolphus College, St. Peter, where he will conduct a campaign for funds for a new college library, the *Journal Lancet* reports.

Educational Program on Vaccination—A campaign has been launched in Minneapolis to educate the public to the need of vaccination. "Before it's too late—vaccinate" is the theme of the program which is being carried out under the endorsement of the Minneapolis Civilian Defense Council and under the direction of the city health commissioner. An intensive publicity program is now under way. Victory Aides can pass every home with a booklet explaining the vaccination situation and urging the cooperation of the public.

MONTANA

Personal—Dr. George B. Wright, Kalispell, has been named health officer of Flathead County to succeed Dr. Albert A. Dodge, Kalispell, who held the position for twenty one years, according to the *Journal Lancet*.

Society News—Dr. Sylvester A. Berens, Seattle, addressed the Silver Bow County Medical Society in Butte, February 23, on "Low Back Pain with Sciatica."—Dr. Roger Anderson, Seattle, discussed "Treatment of Fractures" before the Mount Powell County Medical Society in Anaconda recently.

NEVADA

New Director of Maternal Health—Dr. Julius B. Askey, formerly of San Francisco, has been appointed director of the division of maternal and child health and crippled children's services of the state department of health, Carson City. News papers report that under the appointment Dr. Askey will also serve as acting state epidemiologist. Dr. Frederica A. Keep, Wellington, has been named field physician for the division.

NEW JERSEY

The Martland Lecture—Dr. Cornelius P. Rhoads, New York, will deliver the ninth Harrison Stratford Martland Lecture, March 17, of the Essex County Anatomical and Pathological Society of the Academy of Medicine of Northern New Jersey in Newark. His subject will be "Cancer and the Role Played by Vitamins and Endocrines."

NEW YORK

Only Emergency Cases Accepted at Hospital—Only emergency cases will be accepted in the future at the Elizabeth A. Horton Memorial Hospital, Middletown, because of the critical nursing shortage, the *New York Times* reported on February 21. Elective cases not requiring immediate treatment will be turned down. The patient average at the hospital is 104 a day, it was stated.

New Regulations Govern Blood Donors and Blood Derivatives—The public health council of the state department of health has adopted regulations governing human blood donors, human whole blood, human plasma, human serum or other human blood derivatives used for transfusion purposes. It was announced on March 1. The new regulations are designed to safeguard all phases of blood transfusion, which has become increasingly important because of the widespread use of human blood products both in the armed services and in civilian practice, and will help meet the need for basic standards to insure the safety of human blood products which has been experienced by hospitals and laboratories engaged in processing human blood and in providing transfusion services. The requirements were adopted only after long deliberation by the council and a critical review by representatives of several hospitals, the National Institute of Health, the Office of Civilian Defense, the Medical Society of the State of New York and other interested agencies. The action is said to be the first begun by a state body to govern human blood plasma and other blood derivatives. The subject has been under consideration by the council since 1941, and in June 1942 a committee was appointed to study the subject and prepare a suitable amendment to the sanitary code.

New York City

Second Counseling Service—The mayor's committee on wartime care of children opened its second information and wartime counseling service for working mothers in the Fort Greene Health Center, Brooklyn, February 21. The first service was opened in the Harlem Health Center on January 25.

The Harvey Lecture—Dr Samuel W. Clausen, professor of pediatrics, University of Rochester School of Medicine, will deliver the sixth Harvey Society Lecture of the current series at the New York Academy of Medicine March 18. His subject will be 'The Absorption of Vitamin A and Its Storage in the Tissues.'

Proposed Research Center in Zoological Park—Science reports that the New York Zoological Society is planning to establish a research center in Zoological Park for the study of animal diseases in relation to human disease problems and for a conservation exhibit. The society will receive \$3,000,000 under the terms of a postwar program for the city, it was stated.

Course for Physicians on Kenny Method—On March 29 the New York University College of Medicine will conduct a course for physicians on the modern concepts of poliomyelitis. The course is designed to cover epidemiologic, pathologic and physiologic aspects of poliomyelitis together with a diagnosis of the disease and its treatment by chemical, serologic, orthopedic and physical therapeutic means including the Kenny method. A series of eight lectures at weekly intervals will be given by visiting lecturers from various medical schools throughout the country and demonstrations of the various techniques will be given in the hospitals. A practical course for training physical therapy technicians opened recently at New York University under the auspices of the school of education. Additional information can be obtained from the secretary, New York University College of Medicine, 477 First Avenue.

NORTH CAROLINA

Changes in Health Officers—Dr Samuel P. Burt, Louisburg, has been named health officer of Franklin County to succeed Dr Richard F. Yarborough, Louisburg.—Charles L. Williams Jr., New Bern, assistant surgeon U. S. Public Health Service, has been appointed officer of Lenoir County to succeed Dr Zebulon V. Moseley, Kinston.

Nathalie Gray Bernard Lectures—The first Nathalie Gray Bernard Lectures were given in January by Lieut. Comdr. Albert R. Behnke Jr., M. C., U. S. Navy, on 'The Military Environment Primarily in Relation to Changes in Barometric Pressure.' The lectureship was established last summer by the students and faculty of Bowman Gray School of Medicine of Wake Forest College, Winston-Salem, and will be considered an annual event. Mrs. Bernard, for whom the lectures are named, has given many generous donations to the school.

Anatomist Dies—Francis Huntington Swett, Ph.D., since 1930 professor of anatomy at the Duke University School of Medicine, Durham, died of heart disease on February 10, aged 49. In 1922 Dr. Swett received his doctor of philosophy degree at Yale University, New Haven, Conn., where he had been a member of the faculty since 1919, first as assistant in zoology and later in anatomy. He was on the staff of Johns Hopkins University School of Medicine, Baltimore, from 1922 to 1925, when he joined Vanderbilt University School of Medicine, Nashville, Tenn.

OHIO

Frank E. Bunts Lecture—Dr. J. Eastman Sheehan, New York, delivered the Frank E. Bunts Lecture at the Cleveland Clinic, February 26, on 'Recent Observations of War Wounds in England and Their Care.'

Personal—Dr. Benjamin R. McClellan, Xenia, formerly president of the Ohio State Medical Association, was recently presented with a scroll in recognition of his outstanding service to the community and to his fellow men by the local Rotary Club of which he is a charter member and past president.—Robert S. Shelton, Ph.D., has been promoted to the position of scientific director of the William S. Merrell Company, pharmaceutical manufacturers of Cincinnati, and will be responsible for activities relating to research and product improvement. Since 1934 Dr. Shelton has been organic research chemist with the Merrell Company and associate professor of organic chemistry at the Cincinnati College of Pharmacy. He received his degree of doctor of philosophy at Cornell University in 1933.

OKLAHOMA

Annual Meeting in Oklahoma City—The 1943 meeting of the Oklahoma State Medical Association will be held in Oklahoma City, May 11-12. The theme of the two-day session will be adapted to the war effort as it pertains to the health of the public.

Report on Trachoma Program—The state department of health has issued a report on its program of trachoma control which was instituted July 30, 1941. Since its inception the program has been extended into sixteen counties in the eastern and southern part of the state. Ninety-one clinics were held during the period July 30, 1941 to Dec. 31, 1942. Of the 8,591 patients examined, 1,262 positive cases were found and given treatment.

PENNSYLVANIA

Typhoid Carriers—Sixty-six chronic typhoid carriers were detected in Pennsylvania by the state department of health in 1942, according to *Pennsylvania's Health*.

Philadelphia

Personal—After more than twenty-five years as medical superintendent of the Home for Consumptives, Dr. William J. Enders resigned recently. Dr. Enders, who is now living at Bushkill, Pa., is now consulting physician for the home.—The honorary degrees of doctor of science were awarded by the Philadelphia College of Pharmacy and Science at its recent commencement to Drs. William A. Ferrer, director of the medical research laboratories of Sharp and Dohme Inc., and Harriet L. Hartley of the city department of health.

Pittsburgh

Chemical Award Goes to Dr. King—At a dinner on February 18 in the University Club the Pittsburgh Award given annually for 'outstanding work in chemistry' by the Pittsburgh Section of the American Chemical Society was presented to Charles Glen King, Ph.D., scientific director in charge of research of the Nutrition Foundation, New York. Dr. King is on leave of absence from the University of Pittsburgh as professor of chemistry. Speakers at the dinner included Dr. King, who spoke on recent developments in nutrition; Alexander Silverman, Sc.D., head of the department of chemistry; Charles F. Lewis, LL.D., director of the Buhl Foundation; and Henry J. Heinz II, president of H. J. Heinz and Company.

TEXAS

Changes in Health Personnel—Drs. Charles M. Covington, Alto, was recently appointed epidemiologist of the Travis-Bastrop County Health Unit to succeed Dr. Hugh Shane Austin, who entered military service.—George G. Howard passed assistant surgeon U. S. Public Health Service Reserve has been placed in charge of the Parker and Palo Pinto County Health Unit.—Dr. William O. Funderburk, Elkhart, was recently named health officer of Anderson County, succeeding Dr. Fred E. Felder, Palestine. Dr. Funderburk formerly served as county judge.

UTAH

New Professor of Surgery—Dr. Philip B. Price, who had been professor of surgery at the Cheelo University School of Medicine, Shantung, China, until the hostilities started, has been named head of the newly created department of surgery at the University of Utah School of Medicine, Salt Lake City. Recently Dr. Price has been associate in surgery at the Johns Hopkins University School of Medicine, Baltimore. The University of Utah School of Medicine has heretofore been a two-year school but under a reorganization during the past year has been added to the list of four-year medical schools.

WEST VIRGINIA

Cooperative Medical Education Program Approved—Arrangements have been completed between the board of governors of West Virginia University and the board of visitors of the Medical College of Virginia, Richmond, for the enrollment each year at the latter institution of twenty West Virginia students who complete the two-year medical course at the West Virginia University School of Medicine, Morgantown. After the first year, forty West Virginia medical students will be enrolled at the Medical College of Virginia. The bill (S. B. 85) authorizing the action was passed unanimously by the senate February 23 and by the house of delegates March 3. It was sponsored by the West Virginia State Medical Association and marks the first time in the history of medical education that such an arrangement has been made.

between two medical schools in separate states. The courses of the two medical schools will be coordinated so that the students at West Virginia University will have the same pre-medical training as the students at the Virginia school. The bill further provides that no student shall be eligible to take the courses which may be established unless he has been a bona fide resident of West Virginia for at least five years, has completed the medical course at the university and has been chosen for the purpose by the president and faculty of the West Virginia University School of Medicine.

WISCONSIN

New Director of Health Service and Tuberculosis—Dr. Allan A. Filek, Green Bay, has been appointed director of the division of local health service and tuberculosis control of the state board of health. Dr. Filek graduated at Rush Medical College, Chicago, in 1933 and for the past six years has been district health officer for the sixth sanitary district.

Health Committee for Association of Commerce—A new health committee has been named for the Green Bay Association of Commerce. The committee is now making a survey of the health department activities in the state during the past year, the results of which are to be entered in the national intercity health conservation contest sponsored by the American Public Health Association.

Personal—Dr. Herman F. Weber, Newburg, was honored at a dinner February 3, to celebrate his seventy-fifth birthday. Dr. Weber has been practicing in Newburg for the past forty-seven years. Dr. John J. Rehorst has been appointed health officer of Fond du Lac on a part time basis until a permanent full time appointment can be made filling the vacancy that occurred when Dr. Robert L. Dana obtained a leave of absence to enter military service.

Special Society Election—Dr. Arnold S. Jackson, Madison, was chosen president-elect of the Wisconsin Academy of Surgery at its meeting in Milwaukee, January 27, and Dr. Jaros F. Zivnuska, Milwaukee, was installed as president. Major Jerry W. McRoberts, Sheboygan, M. C., U. S. Army, was the retiring president. Other officers include Dr. Gervase S. Flaherty, South Milwaukee, secretary, and Dr. James G. Garland, Milwaukee, treasurer. The next meeting of the academy will be held in Madison, May 19.

GENERAL

Fellowships for Research on Quinine—Two fellowships are offered by the Cinchona Products Institute of New York for clinical or pharmacologic research on quinine or the other alkaloids of cinchona. They carry a yearly stipend of \$2,000 plus necessary laboratory or routine expenses. Further details may be secured from Cinchona Products Institute, Inc., 10 Rockefeller Plaza, New York.

New Executive Secretary of American Hospital Association—Mr. George Puffer Bugbee, superintendent of City Hospital, Cleveland, has been appointed executive secretary of the American Hospital Association, effective May 1. He will succeed Dr. Bert Caldwell, who has been named secretary emeritus. Mr. Bugbee has served as credit and office manager and assistant director of the University Hospital, Ann Arbor, Mich.

Dr. Busch to Direct Red Cross for Eastern Area—Dr. John F. Busch, since 1937 associated with the division of tuberculosis control of the Georgia Department of Public Health, Atlanta, has been appointed director of medical and health service for the Eastern Area of the American Red Cross, with headquarters in Alexandria, Va. Dr. Busch graduated at the Medical College of the State of South Carolina, Charleston, in 1927.

Conference of Industrial Hygienists—The sixth annual meeting of the National Conference of Governmental Industrial Hygienists will be held at the Hotel Seneca, Rochester, N. Y., May 24, followed by meetings of the American Industrial Hygiene Association and the American Association of Industrial Physicians and Surgeons, May 25-27. These sessions were originally scheduled for May 17-20 but because of conflict with other conferences the dates were changed, according to *Industrial Hygiene*. On May 26 a joint session of the three associations with the New York State Associated Industries will be held at the Eastman Theater.

Examinations of Orthoptic Council—The American Orthoptic Council announces that written examinations will be held at various cities in the country on September 9. Only those passing the written examination will be permitted to take the oral and practical tests in Chicago on October 9.

Applications on official forms must be received before August 1. All communications should be addressed to the American Orthoptic Council, 23 East Seventy-Ninth Street, New York. The council was organized in 1938 by a group of ophthalmologists, representing the Section on Ophthalmology of the American Medical Association, and the American Academy of Ophthalmology and Otolaryngology, to supervise the training of technicians.

Pan American Congress of Ophthalmology—The triennial meeting of the Pan American Congress of Ophthalmology will be held in Montevideo, Uruguay, November 4-9, 1943, under the presidency of Dr. Harry S. Gradle, Chicago. A recent announcement states that in spite of the present world condition it was decided to go ahead with the organization and preparation of scientific work for the meeting. If by June 1943 the world situation still seems unfavorable, the meeting will be postponed until November 1944. The first day of the session has been designated as the "inaugural session." The second day will be given to a consideration of social ophthalmology, the morning session to cover 'Prevention of Blindness in the Americas' and the afternoon 'The Status of Trachoma in the Americas.' The third day will be devoted to research in ophthalmology, eight studies to be selected by the committee on arrangements. The fourth day of the session will be given over to excursions and festivities. The session will be concluded with a consideration of glaucoma, individual topics to be 'The Prehypertensive State—Its Diagnosis and Treatment,' 'New Ideas on Glaucoma Derived from Gonioscopy,' 'Estimation and Mechanism of the Destructive Effects of Ocular Hypertension and "Surgical Intervention in Glaucoma—How Far Can Medical Treatment be Continued".'

Few Fatalities Charged to Exposure to Cold—Fatalities resulting directly from exposure to cold by actually freezing to death or suffering severe frostbite in homes inadequately or poorly heated are few and far between, according to a release from the Metropolitan Life Insurance Company. There is no indication that the fuel shortage will add materially to the toll this year, it was stated. Around 350 deaths each year on the average are charged to exposure to excessive cold. Where death actually occurs from this cause it is usually outdoors and the victim often is a person under the influence of liquor or mentally deranged, it was stated. Where death from exposure does occur in the home, past experience shows that the victim in most cases was either very old or a sick person, living alone and unable on account of an infirmity to tend the fire. A study covering the years 1933-1940 showed that some of the Eastern states critically affected this winter by fuel shortages registered death rates from cold below the general average of 28 per million observed in the United States as a whole. The rates were 16 in both New York and New Jersey, 19 in Massachusetts and 27 in Connecticut. Higher rates than the average occurred in Vermont, 31, and New Hampshire, 36, while the highest rates among those states affected by the wartime heating problem were recorded in Maryland, 43; Rhode Island, 45; and Maine, 66. The highest rates in the country prevailed in the mountain states of Nevada, 240; Montana, 149; and Wyoming, 144. North Dakota, 101, is the only other state with a rate exceeding ten deaths per million of population. The lowest rates were recorded in California, 07, and the District of Columbia, 06. Referring to an analysis made some years ago of the records of deaths ascribed to excessive cold among their company's industrial policyholders, it was stated that more than one third of the victims were reported as being either under the influence of intoxicating liquors or mentally deranged. These individuals were found in the open where they had been exposed to cold weather for long periods. A number of deaths occurred among persons who had fallen down and on account of age were unable to get up and were subjected to prolonged exposure to cold. Others succumbed on hunting or fishing trips when lost in a storm or while at work in the open.

CORRECTIONS

Mental Symptoms Following Use of Atabrine—In the Current Comment under the foregoing title in *THE JOURNAL*, March 6, page 765, in the sixth line from the end the word "malaria" should be substituted for the words "quinine daily."

Superficial Vascularization of the Cornea—In the abstract of Dr. H. R. Sandstead's article in *THE JOURNAL*, February 20, page 624, entitled "Superficial Vascularization of Cornea," the fourth line from the bottom of the second column should read "5 mg of riboflavin twice daily for forty-nine days" or 10 mg daily.

Infective Hepatitis in the War

Jaundice is one of the disorders of armies in the field. In the last great war a few of the outbreaks were traced to *Leptospira icterohemorrhagica* (spirochetal jaundice) but others defied investigation. The coincident prevalence of intestinal disease led to the view that the jaundice was due to ascending catarrh of the bile passages and many were labeled catarrhal jaundice, but in fatal cases the liver sometimes showed a focal necrosis, never involving the bile passages, which pointed to systemic infection. Except for one outbreak in Scandinavia in 1925-1927, no comparable outbreaks were seen until the disease appeared again in the British Expeditionary Force in 1939. However, it has now been noted among troops in the United Kingdom, the United States, northern Ireland, West Africa, Malta, Iceland and especially the Middle East. Its incidence in enemy occupied Europe is thought to be considerable.

In an army medical bulletin it is stated that new and valuable facts have come to light about infective hepatitis since 1936 when jaundice developed in a group of people inoculated several months before with yellow fever vaccine. Since then children and others passively immunized with mumps and measles convalescent serum have developed similar jaundice, which they have sometimes transmitted to contacts and laboratory workers handling serum from patients with the disease. American troops immunized with certain batches of yellow fever vaccine have also been affected, and jaundice has been discovered among the donors of the vaccine. It has been shown that at least one of the causative organisms of infective hepatitis can (1) pass through bacteria trapping filters, (2) withstand the action of phenol, freezing and drying and (3) be propagated in serum-tyrode chicken embryo medium. Thus it behaves as a virus and further examination is handicapped by the fact that it has not been transmitted to any animal.

The incubation period of the natural disease is about a month, but after serum as much as three or four months—a difference not explained. The general immunity appears to be high, only about 10 per cent of exposed persons show obvious jaundice and after injection of infected serum less than 30 per cent. It seems possible that the jaundice seen from time to time in those taking arsphenamine is due to the same virus attacking a liver damaged by the drug. The same may hold for the hepatitis attributed to trinitrotoluene and other industrial poisons. The diagnosis may be easy during an outbreak or after immunization but may be difficult in single cases. Leptospiral jaundice may be excluded by animal inoculation, serologic tests or the blood picture. The death rate is low and death is unusual before the second or third week.

Increased Food Restrictions to Save Shipping

In order to devote as much shipping as possible to the carriage of military supplies, the consumption of food is to be further scaled down. Lord Woolton, minister of food, says that in 1943 there will be a continuance of the tightening up process already in force in 1942. Restriction was achieved mainly by applying points rationing to several more foods and reducing on July 26 each consumer's points from 24 to 20 a month. At the same time the cheese allowance was doubled to the generous one of half a pound a week, which may have to be reduced soon. When the year 1942 opened points rationing was confined to canned meats, fish and beans. During the year rice, sago, tapioca, dried peas, beans and lentils, dried

fruits, canned fruits and vegetables, condensed milk, cereal breakfast foods, syrup and molasses, biscuits and rolled or flaked oats were added.

The Ministry of Food has made its contribution to shipping needs by trimming imports, mainly by bringing in concentrated foods, such as dried egg instead of eggs in the shell and by pushing the consumption of home produced foods such as potatoes, against those imported. The ministry helped to insure a cheap and plentiful supply of potatoes and tried by various means, including a rise in price, to discourage consumption of bread. Wheat makes up a large part of our food imports, and to reduce this amount the extraction of flour was increased from 75 to 85 per cent, and white bread disappeared for the duration of the war. Two additional ways of saving on grain imports remain. To increase the extraction of wheat to 90 per cent or more would encounter the same vigorous opposition as did the increase to 85 per cent, the addition of home produced oats and barley to the national flour has been decided on.

"Iatrogenic Disorders"

Sir Arthur Hurst has introduced into medicine the term "iatrogenic disorders," iatrogenic being derived from Greek words meaning "generated by the physician" but surgeons, radiologists and pathologists are included in his criticism. In a lecture delivered to the Medical Society of the Middlesex Hospital on the subject he began by pointing out that in hysteria the patients are so suggestible that the symptoms largely depend on or are the result of the method of examination. Investigating the diminution of the visual fields in a case of hysteria the physician will find as he moves around the clock that the field will become progressively narrowed in spiral fashion ending in practically no visual field. But if then he plots the field, moving the spot from the middle of the tiny field toward the periphery, asking the patient when he can no longer see the spot, he will be able to unwind the field until the normal visual field returns. Similarly paresthesia of the arm or leg in a hysterical paralysis is the patient's idea of what the physician ought to find in a case of organic paralysis.

The terms 'soldier's heart' and 'effort syndrome' when tentatively applied to cases, suggest things to the patient who becomes more likely to succumb to the malady. An example was a gardener who enjoyed perfect health until he was examined by a medical board for the army. Extrasystoles were found and thought to be of some significance. He was sent to London to be electrocardiographed and thence to a heart hospital for further investigation. He saw constantly around him the main clinical symptoms of cardiac cases and picked up the "atmosphere." Soon he was experiencing these same symptoms himself, his state being induced purely by suggestion and the initial fixation of his attention on his heart by frequent examinations and the flourishing of stethoscopes and other fearsome instruments. Sir Arthur warned his audience to be very careful about telling patients about their blood pressure as this often caused unnecessary introspection. He knew of a spa full of people worried about their blood pressure. Those with high pressure took the waters to get it down; those with low pressure took the waters to get it up!

Mucous colitis has always been regarded by Hurst as a mythical malady. He has pointed out that mucous membranes secrete mucus for their own protection. The clear mucus passed with scybala protects the colonic mucous membrane from mechanical injury, that passed with unformed stools after a purgative protect it from chemical injury. This mucus contains no inflammatory cells, endoscopy reveals a healthy mucous membrane. To diagnose mucous colitis is to create an anxiety neurosis. People will luxuriate in it and their chief aim in life becomes a minute examination of the proportion of mucus in their stools and how much can be coaxed out of the rectum.

gation Bowel neurosis is largely the product of physicians giving patients the impression that their bowels are swamps of putrid matter bearable only if constantly purged and swilled out with frequent and copious floods of water Radiologists are also responsible for mischief The x-ray report of "gastroptosis, translated to the patient as "dropped stomach," con-jures up to him terrible things Treatment with a belt forces the stomach farther into the pelvis It is not borne in mind that some stomachs are longer than others, just as some people's noses are The x-ray diagnosis of "duodentitis," which is sometimes passed on to the patient, is purely iatrogenic

Surgeons who fall back on "chronic appendicitis" as a diagnosis are really admitting failure One of the almost constant signs of chronic cholecystitis is an appendix scar The diagnosis of adhesions to explain the recurrence of pain after appendectomy is another sign that the real trouble has not been reached

Finally, Sir Arthur dealt with a subject which he has made his own—peptic ulcer Here as in many other cases, the use of x-rays has made us slack in eliciting proper histories and physical signs before making a diagnosis, gastroscopy should be done in all cases diagnosed The process of a barium meal is liable to start a functional dyspepsia, and two barium meals are certain to People once assured that they have no ulcer should be prevented from trying to obtain a different diagnosis at another hospital Anastomotic ulcers and their serious complications are purely the result of surgery Partial gastrectomy in a straightforward case is so uncertain of producing permanent cure as to make it not warrantable Only total gastrectomy is certain of producing cure, and rigid medical treatment is the next best thing

The Health of Women War Workers

In its report, the Select Committee on National Expenditure deals with the health and welfare of women in factories It asks the government to secure a satisfactory medical service in all factories doing government work Greater use should be made of women doctors A central industrial health advisory committee should be set up to advise on all questions of industrial health and on the coordination of medical services to meet the requirements of the war effort Regional industrial health advisory committees should also be set up to advise the Ministry of Labor These committees, working in cooperation with medical organizations, could do much to reduce the incidence both of industrial disease and of general sickness among industrial workers

The estimated increase in the number of women in industry (excluding civil defense) in the first three years of the war is over a million and a half Taking munitions and certain essential industries and services together, the increase is nearly two million The number of recruits with no previous experience of factory life is large and there is a considerable proportion of married women with their own special problems Except in the case of ordnance factories and certain private undertakings there has been no selective examination on joining Had the necessary medical staff been available, the committee would have strongly recommended that this be done It draws attention to the waste of public money in transferring to factories away from home of women not physically fit for factory work In considering the most suitable length of the working day, regard must be paid to the time that women are often obliged to spend on domestic duties and shopping, as well as in travel to and from their place of work Many married women are now doing the equivalent of two full time jobs Instances are given of women working twelve hours a day, spending two or three hours in traveling and on top of this undertaking household duties It is obvious why under such circumstances sickness should be more frequent among women than among men workers

The Movement Toward Compulsory Health Insurance in Canada

In the speech from the throne, presented at the opening of Parliament a month ago, there appeared a clause which indicated that the government proposed to take action to provide a comprehensive national plan of social insurance, including health insurance For the past eighteen months an Advisory Committee on Health Insurance, set up within the Department of Pensions and National Health, has been studying proposals relating to health insurance, having in view the drafting of legislation, either federal or provincial or a combination of the two, to provide health insurance for the Canadian people Putting the two preceding facts together, there would appear to be every indication that health insurance legislation will be discussed in the Parliament of Canada this coming session

During the past fifteen years the Canadian Medical Association has given considerable attention to health insurance and allied problems Study committees were established throughout the Dominion The general secretary of the association was sent to Europe in 1937 to visit a number of countries where health insurance was in operation The Canadian Medical Association has long since gone on record with respect to the principles which should be incorporated in health insurance legislation when and if such legislation becomes effective The association had not, however, up until January 1943, expressed itself either in favor of or opposed to the inauguration of health insurance in Canada

Realizing that health insurance was apparently imminent and that a very high percentage of the people of our country were in favor of some such measure, the general council of the Canadian Medical Association was convened in special session in Ottawa on January 17 and 18 to resurvey its position in respect to the problem The attendance was seventy eight, with all the provinces well represented At the end of two days' discussion, the general council unanimously adopted the following resolution

- WHEREAS The objects of the Canadian Medical Association are
- 1 The promotion of health and the prevention of disease
 - 2 The improvement of health services
 - 3 The performance of such other lawful things as are incidental or conducive to the welfare of the public and

WHEREAS The Canadian Medical Association is keenly conscious of the desirability of providing adequate health services to all the people of Canada and

WHEREAS The Canadian Medical Association has for many years been studying plans for the securing of such health services therefore be it

Resolved That

- 1 The Canadian Medical Association approves the adoption of the principle of health insurance
- 2 The Canadian Medical Association favors a plan of health insurance which will secure the development and provision of the highest standard of health services preventive and curative if such plan be fair both to the insured and to all those rendering the service

A select committee of the House of Commons has been established to study the matter Representatives of the Canadian Medical Association will appear before that committee and endeavor to interpret the views of the medical profession of Canada

Summing up, it may be said that the Canadian Medical Association takes this position in respect to the subject

1 That, in whatever plan or plans may be devised to provide health services to the people of Canada, a standard of service equal to or higher than that which now obtains should be guaranteed, and

2 That the financial arrangements which will be necessary to implement an ideal plan must be fair both to those who provide the services and to those who are served

Deaths

Joseph Francis Elward * Washington, D C, Georgetown University School of Medicine, Washington 1919, specialist certified by the American Board of Radiology, Inc also a pharmacist, formerly clinical instructor in radiology at the George Washington University School of Medicine and associate professor of roentgenology at his alma mater, in 1938 was elected secretary of the American Therapeutic Society, member of the American Roentgen Ray Society, Radiological Society of North America, Inc, American College of Radiology and the American Radium Society, served during World War I served as roentgenologist to the Sibley Memorial, George Washington University and National Homeopathic hospitals, formerly consultant in roentgenology to the U S Veterans Administration, aged 52, died, February 6, in Plains, Pa, of coronary thrombosis

Wilhelm Siegmund Frei, New York, Georg August-Universität Medizinische Fakultät, Göttingen, Prussia, Germany, 1913 in 1911 served as an assistant at the Robert Koch Institute for Infectious Diseases in Berlin during World War I served in the Hamburg Bacteriological Laboratory and as an army medical officer, from 1919 to 1929 was an assistant at the University Clinic of Dermatology of Breslau, in 1923 was lecturer and in 1926 professor of dermatology at the Breslau University, in 1929 was made physician in chief of the dermatologic department of Berlin-Spandau Municipal Hospital, devised the diagnostic Frei test for venereal lymphogranuloma, in 1937 was appointed resident physician in dermatology holding this post until July 1, 1938 at the Montefiore Hospital, where he died, January 27, of tuberculosis, aged 57

Joseph Andrew Hyams * New York, Columbia University College of Physicians and Surgeons New York 1905, specialist certified by the American Board of Urology, Inc member of the American Urological Association, fellow of the American College of Surgeons, formerly associate professor of clinical urology at the New York Post-Graduate Medical School, Columbia University served as a lieutenant in the medical corps of the U S Army during World War I, attending urologist and director of the service of urology at the New York Post Graduate Medical School and Hospital and Dispensary director of the department of urology at the Gouverneur Hospital, consulting urologist, All Souls Hospital, Morristown, N J, aged 58, died, January 26, of coronary thrombosis

Jefferson L Angell, Kingsville, Mo, Ensworth Medical College St Joseph, 1893 aged 85, died, January 7, in Kansas City of uremia

Gordon C Anson, Ironton, Mo Homeopathic Medical College of Missouri, St Louis, 1900, aged 64, died, December 9 in Bonne Terre of angina pectoris

Charles Willett Austene, Centralia, Mo, University of Missouri School of Medicine, Columbia, 1901, aged 66 died January 13, in a hospital at Fulton of pneumonia

John Carleton Bachop, Sheakleyville, Pa, University of Michigan Department of Medicine and Surgery, Ann Arbor, 1883, aged 88 died, January 28, of coronary occlusion

William E Barron * Addison N Y College of Physicians and Surgeons, Baltimore, 1891, formerly served as mayor, past president of the Steuben County Medical Society, at one time surgeon for the Buffalo and Susquehanna Railroad, aged 76, died December 21, in the Veterans Administration Facility Bay Pines, Fla

Charles Bickel, Trenton, Mo, Medico-Chirurgical College of Kansas City, Mo, 1902 aged 72 died, February 8, in the Cullers Hospital of cerebral hemorrhage

Henry Lyons Bienenfeld, Brooklyn University of the City of New York Medical Department, 1884, for many years chairman of local school board number 20 in New York and at one time health officer of the Port of New York, aged 86, died, January 5, in the Israel Zion Hospital

Siegfried Blach, Brooklyn, Universität Heidelberg Medizinische Fakultät, Baden Germany, 1923, member of the Medical Society of the State of New York, aged 42, died, December 11

Walter Ernst Boehm * Richmond Hill, N Y Schlesische-Friedrich-Wilhelms-Universität Medizinische Fakultät, Breslau Prussia, Germany, 1922, aged 46, died, January 6, in the Flower and Fifth Avenue Hospitals of carcinoma

Jacques de Lorimer Bourgeois, Montreal Que Canada, University of Montreal Faculty of Medicine, 1939, on Dec 1, 1940 was commissioned a surgeon lieutenant in the Royal

Canadian Naval Volunteer Reserve, aged 29, died, November 8, as the result of enemy shell fire while he was operating on an American soldier on board ship at Oran, North Africa

David Ritehey Braden * Mission, Kan, St Louis University School of Medicine, 1920, member of the Missouri State Medical Association in 1921 was connected with the U S Public Health Service, for five years assistant medical director of the Illinois Life Insurance Company in Chicago member of the Myers Clinic in Kansas City, Mo, from 1927 to 1937, aged 54 died suddenly, January 19, of coronary occlusion

George Cecil Browne, Oakland, Calif College of Physicians and Surgeons, Baltimore, 1899 member of the California Medical Association, served as medical adviser of draft board number 6 during World War I, recently examining physician for draft board number 59 on the staff of the Alameda (Calif) Hospital aged 66, died, January 20 of heart disease

Howard Sheldon Bulkeley * Rhinebeck, N Y, University and Bellevue Hospital Medical College New York 1912 for several years town health officer aged 56 died, January 17, in the Northern Dutchess Health Service Center

Benjamin Brabson Cates, Knoxville, Tenn University of Pennsylvania Department of Medicine Philadelphia 1888 member of the Tennessee State Medical Association formerly professor of principles and practice of surgery and clinical surgery at the Tennessee Medical College, served on the staff of the Knoxville General and St Mary's hospitals for many years, aged 77, died, January 21, of pneumonia and myocarditis

George Edwin Cecil, Hazlehurst Miss University of Tennessee Medical Department Nashville, 1893, served during World War I, aged 75, died in January

James Thomas Adam Clarke, Winnipeg, Man Canada Manitoba Medical College, Winnipeg, 1901, aged 69 died January 23, of coronary occlusion

William Hallett Cole, New Germany N S, Canada Medical School of Maine, Portland, 1883, aged 87 died December 2

Asa Weston Collins, San Francisco Cooper Medical College, San Francisco 1903, member of the California Medical Association, formerly adjunct professor of surgery at the College of Physicians and Surgeons of San Francisco was made a Chevalier of the Legion of Honor by the French government for many years' service as chief surgeon of the French Hospital served during World War I fellow of the American College of Surgeons, aged 67, died January 19 in Palo Alto Calif, of heart disease

William Edward Costello, Dubuque Iowa State University of Iowa College of Medicine, Iowa City 1894, member of the Iowa State Medical Society, aged 76, died, January 17, of heart disease

Archibald Nelson Currie, Kalispell, Mont, Rush Medical College, Chicago, 1899, aged 68, died recently of carcinoma of the lung

Edward Gates Davis, Kansas City Kan College of Physicians and Surgeons, Medical Department, Kansas City University, Kansas City, Kan, 1898 member of the Kansas Medical Society, aged 77, died, January 23 in the Bethany Hospital of arteriosclerosis

Madison Pope Deadwyler, Maysville, Ga, Jefferson Medical College of Philadelphia, 1897, served as mayor of Maysville for many years, aged 69, died December 3, of diabetes mellitus

Cornelius J Donovan, Lovington, Ill, St Louis College of Physicians and Surgeons 1893, aged 72, died, January 15 in St Mary's Hospital, Decatur, of cerebral hemorrhage

John Clark Farr, Hoboken, N J, Long Island College Hospital, Brooklyn, 1902, member of the Medical Society of New Jersey, formerly medical director of a sanatorium bearing his name, served on the staffs of the Hasbrouck Heights (N J) Hospital, St Mary's Hospital, Hoboken, and the North Hudson Hospital, Weehawken, aged 73, died, January 24, of cerebral hemorrhage

James Vincent Foley, Pocatello, Idaho, University of Tennessee College of Medicine, Memphis 1931 member of the Idaho State Medical Association director of the Bannock County Health Unit, first lieutenant in the medical reserve corps of the U S Army not on active duty, aged 36 died January 11, in the Pocatello General Hospital of a subdural hemorrhage from a basal skull fracture incurred in a fall

Edmond Bland Ballard Fulliam Jr, Muscatine, Iowa Bennett Medical College, Chicago 1913, member of the Iowa State Medical Society formerly health officer of Muscatine,

served overseas in the medical corps of the U S Army during World War I, aged 51, died, January 10, in Fort Lauderdale, Fla of cerebral hemorrhage

Frederick Carl Gunkel, Cincinnati Medical College of Ohio, Cincinnati, 1884, aged 83, died, January 22, of chronic valvular heart disease

Flora Cornelia Moss Jackson, Peoria, Ill., State University of Iowa College of Homeopathic Medicine Iowa City, 1895, aged 80, died, January 2 of acute cardiac dilatation

Amelia R Keller, Indianapolis Central College of Physicians and Surgeons Indianapolis 1893, at one time assistant professor of pediatrics at the Indiana University School of Medicine aged 72, died, January 28, in the Indianapolis City Hospital of coronary occlusion

Henry Cowles Kent, Indianola Miss, Vanderbilt University School of Medicine Nashville Tenn 1893, veteran of the Spanish American War and World War I aged 71 died January 15 in the Veterans Administration Facility, Memphis, Tenn of coronary occlusion

Robert McKee Lapsley * Keokuk, Iowa College of Physicians and Surgeons, Keokuk 1890 Rush Medical College Chicago 1891 at one time professor of ophthalmology otology and rhinolaryngology and treasurer of Keokuk Medical College member of the American Academy of Ophthalmology and Otolaryngology fellow of the American College of Surgeons aged 72 on the staff of the Graham Hospital president of the staff of St Josephs Hospital, where he died, January 5, of military tuberculosis

John Newton Franklin Latimer, Atlanta Ga Meharry Medical College Nashville, Tenn 1908 aged 67, died, January 17 of septicemia

David Edward Lenker, Sunbury Pa Jefferson Medical College of Philadelphia 1888 served as Northumberland County jail physician aged 80 died December 25 in the Mary M Packer Hospital of cerebral hemorrhage

Archibald Stuart Lewis, Greensburg Ky University of Louisville (Ky) Medical Department 1885 aged 81 died January 4 of injuries received when struck by a truck

Hiram John Lloyd * Mankato, Minn Chicago College of Medicine and Surgery, 1911 on the staffs of the Immanuel Hospital and St Josephs Hospital, where he died December 14, of a cerebral accident aged 65

Charles Allen Luce, Amityville, N Y Bellevue Hospital Medical College New York 1890, member of the Medical Society of the State of New York served as acting assistant surgeon in the U S Public Health Service for many years president and at one time director of the First National Bank and Trust Company, aged 77, was found dead, January 21, of a self-inflicted bullet wound

Harry Kenyon McCall, Sioux City Iowa College of Physicians and Surgeons of Chicago School of Medicine of the University of Illinois, 1901, aged 66, died, January 12, of arteriosclerosis

Albert Newton Mackey, Aledo, Ill Bellevue Hospital Medical College, New York 1893, served during World War I, aged 79, died, February 11, of coronary thrombosis

George Jefferson Mancill, Indianola, Miss, Memphis (Tenn) Hospital Medical College, 1911, member of the Mississippi State Medical Association served as a first lieutenant in the medical corps of the U S Army during World War I, recently an examining physician for the Sunflower County Selective Service System and chairman of the county infantile paralysis foundation, aged 54, died January 15, in the King's Daughters Hospital, Greenville, of lobar pneumonia

Freeman Simeon Messenger, Middleton N S, Canada, University of the City of New York Medical Department, New York, 1893, served as mayor through two terms and for many years as a member of the town council a coroner for Annapolis County and a member of the provincial medical board aged 75, died, November 24

Alexander J Nielson, Salt Lake City George Washington University School of Medicine Washington, D C 1907 at one time a school teacher in the public schools, aged 71, died, January 16, of coronary occlusion

William Henry Norrish, Kenmore, N Y Niagara University Medical Department Buffalo 1890, aged 77, died December 27, of cerebral hemorrhage

John Aloysius O'Mara * Spring Lake, N J, Georgetown University School of Medicine Washington D C, 1933, an associate obstetrician at the Fithkin Memorial Hospital Nep-

tune, member of the medical draft board number 6 Monmouth County, aged 36, died, January 20, of coronary thrombosis

Kristinn Olafson, Cando, N D, University of Manitoba Faculty of Medicine, Winnipeg, Man, Canada, 1933, member of the North Dakota State Medical Association, aged 40 died accidentally, December 2, of carbon monoxide poisoning

Levon Papazian, Nelson, B C, Canada, McGill University Faculty of Medicine, Montreal, Que, 1943, was granted a posthumous degree from McGill University on February 3 aged 23 died, December 24

Frank Placide Perret, Jeanerette, La, Tulane University of Louisiana School of Medicine, New Orleans, 1928 member of the Louisiana State Medical Society, aged 38, died, January 10, of hemorrhage and peptic ulcer

Don Preston Peters, Lynchburg Va University of Virginia Department of Medicine, Charlottesville, 1902, member of the Medical Society of Virginia, served during World War I, fellow of the American College of Surgeons, member of the visiting surgical staff, Virginia Baptist, Marshall Lodge Memorial Guggenheimer Memorial and Lynchburg General hospitals surgeon State Colony, Colony, aged 65 died, January 20, of coronary thrombosis

George Franklin Porter, Centerville, Kan, University Medical College of Kansas City Mo, 1910, member of the Kansas Medical Society served in the medical corps of the U S Army during World War I, aged 56, died, December 7, of acute cardiac dilatation

Clarence Quinan * San Francisco, Calif Washington University School of Medicine, St Louis, 1897, lieutenant colonel in the medical reserve corps of the U S Army not on active duty, veteran of the Spanish American War and World War I from 1901 to 1908 instructor in medicine and assistant professor of pathology at the University of California Medical School, serving in the latter position and as acting head of the department 1909-1910, aged 72, died, December 9 in Los Gatos of cerebral hemorrhage

Theron S Reynolds, Bancroft, Mich Homeopathic Medical College of Missouri, St Louis, 1898, aged 74, died December 3 of heart disease

Eugene Stanley Robbins, New Bedford Mass Bellevue Hospital Medical College, New York 1894, member of the Massachusetts Medical Society, aged 70, died, January 18, in West Palm Beach, Fla, of cerebral hemorrhage

William A Robertson, St Joseph, Mo, Marion Sims College of Medicine St Louis 1897 formerly county physician aged 70 on the staff of the Missouri Methodist Hospital, where he died, January 10, of coronary occlusion and arteriosclerosis

Solucius L Russell, Yadkinville N C University of Tennessee Medical Department Nashville 1892 aged 84, died, January 17, of hypertensive heart disease with right hemiplegia

Henry Middleton Rutledge IV * Laurens, S C Medical College of the State of South Carolina, Charleston 1936, aged 32 on the staff of the Laurens County Hospital, where he died, January 18, of pneumonia following injuries received in a traffic accident

Charles Edward Scharf * Chicago Chicago College of Medicine and Surgery, 1913, served as physician for the health department of Chicago, aged 58, one of the original founders member of the board of directors and attending surgeon Belmont Community Hospital, where he died, January 25 of cardiorenal disease

Irving Sherman * Brooklyn, Tufts College Medical School Boston 1924, specialist certified by the American Board of Pathology, Inc blood transfusionist and hematologist to the Israel Zion, Brooklyn Women's Adelphi and the Brooklyn Doctors hospitals, aged 43, died, January 24, of lympho sarcoma

Edwin Dudley Smith, Woodmere N Y, College of Physicians and Surgeons, New York, 1889, aged 74, died, January 16 of cerebral hemorrhage

Ira Mason Smith, Princeton W Va, Atlantic Medical College Baltimore, 1908, member of the West Virginia State Medical Association, aged 66, on the staff of the Mercer Memorial Hospital, where he died, January 10, of myocarditis and heart block

James Ritchie Sparkman, Spartanburg S C, Medical College of the State of South Carolina, Charleston, 1907 member of the South Carolina Medical Association, aged 58 died January 4 of hypertensive heart disease

John Gurdon Steele, Bristol, Pa., University of Pennsylvania Department of Medicine, Philadelphia, 1898, member of the Medical Society of the State of Pennsylvania, served in the medical corps of the U S Army during World War I, aged 68, died, January 27, in the Rosneath Farms Sanatorium, Philadelphia, of chronic myocarditis

Robert G Steele, Mcmore, Ohio, Western Reserve University Medical Department, Cleveland, 1883, in 1933 a dinner was given by the Seneca County Medical Society in recognition of his fifty years in the practice of medicine, aged 85, died, January 15, of arteriosclerosis and acute enterocolitis

Forrest Ray Stewart, Ironton, Ohio, Ohio State University College of Medicine, Columbus, 1917, member of the Ohio State Medical Association, past president of the Lawrence County Medical Society, member of the state house of representatives 1941-1942 and elected again for 1943-1944, during World War I served overseas as a captain, U S Army, in the 145th ambulance corps, formerly health officer of Lawrence County, on the staff of the Lawrence County General Hospital, aged 53, died, January 18, of coronary thrombosis

Edwin Pangman Stickney @ Arlington, Mass., Harvard Medical School, Boston, 1892, member of the New England Pediatric Society, on the staff of the Symmes Arlington Hospital, aged 80, died, January 8, of cerebral hemorrhage

Howard George Stimus, Camden, N J, Jefferson Medical College of Philadelphia, 1902, member of the Medical Society of New Jersey, also a pharmacist, aged 67, died, January 17, in the Cooper Hospital of cerebral hemorrhage and hypertension

Frank Montgomery Stites @ Hopkinsville, Ky., University of Louisville Medical Department, 1889, aged 74, died, January 26, of coronary occlusion

Frances Sumner Janney Stoddart, Riverton N J, Woman's Medical College of Pennsylvania, Philadelphia, 1890, aged 76, died, January 26, of cerebral hemorrhage

John William Stofer, Gallup, N M, University Medical College of Kansas City, Mo, 1908, member and past president of the New Mexico Medical Society, past president and for many years secretary-treasurer of the McKinley County Medical Society, fellow of the American College of Physicians, local surgeon for the Atchison, Topeka and Santa Fe Railroad, member of the staff of St Mary's Hospital, aged 63, died, January 16, of cerebral hemorrhage

David Owen Thomas @ New Kensington, Pa., Baltimore Medical College, 1905, served overseas during World War I, colonel in the medical reserve corps of the U S Army not on active duty, served as head of the Office of Civilian Defense in New Kensington, aged 70, died, January 14, in the Veterans Administration Facility, Aspinwall, of myocarditis

Samuel Gately Tracy, New York, Bellevue Hospital Medical College, New York, 1890, aged 75, died, December 7, of heart disease and bronchopneumonia

Hoyte Sale Trice, Tupelo, Miss., Medical Department of Tulane University of Louisiana, New Orleans, 1910, aged 58, died, January 5, of congestive heart disease

John Charles Tritch, Findlay, Ohio, Homeopathic Hospital College, Cleveland, 1877, member of the Ohio State Medical Association, fellow of the American College of Surgeons, past president of the Hancock County Medical Society, served as a member of the board of education of Findlay and as coroner of Hancock County, consulting chief of staff and member of the surgical staff of the Findlay Hospital, where he died, January 21, of arteriosclerosis, aged 85

Robert Carroll Walker, Waycross, Ga., University of Pennsylvania School of Medicine, Philadelphia, 1914, member of the Medical Association of Georgia, past president of the Ware County Medical Society, served during World War I and as city physician, on the staff of the Ware County Hospital, aged 53, died, January 9, of pulmonary tuberculosis

Charles Curtis Wallin, Lewistown, Mont., University of Michigan Department of Medicine, Ann Arbor, 1902, member of the Montana State Medical Association, veteran of the Spanish-American War, health officer of Fergus County and of Lewistown, at one time county physician and deputy health officer of Meagher County, aged 67, died, January 5, in St Joseph's Hospital of acute leukemia and pneumonia

Thomas Pinckney Waring @ Savannah Ga., College of Physicians and Surgeons, New York, 1892, member of the House of Delegates of the American Medical Association in 1906, member of the Southern Surgical Association, fellow of the American College of Surgeons, medical director and owner of the Oglethorpe Sanatorium, formerly superintendent and surgeon in charge of the Telfair Hospital, served as visit-

ing surgeon to Savannah and St Joseph's hospitals, aged 75, died, January 8

George Maxey Watkins, Walnut Ridge, Ark., Memphis (Tenn.) Hospital Medical College, 1909, member of the Arkansas Medical Society, major in the medical reserve corps of the U S Army not on active duty, served with the same rank during World War I, aged 69, died, November 29, of cerebral hemorrhage

Miles Weller, Beverly Hills, Calif., Denver and Gross College of Medicine, 1904, at one time taught obstetrics at the Gross Medical College in Denver, aged 77, died, January 12, of cardiac asthma

John W Wells, Magnolia Ky., University of Louisville (Ky.) Medical Department, 1894, on the board of the T J Samson Community Hospital, Glasgow, aged 72, died, December 17, of angina pectoris

Lightfoot A West, Memphis, Tenn., Meharry Medical College, Nashville, 1907, surgeon on the staff of the Collins Chapel Connectional Hospital and formerly surgeon on the staff of the Mercy Hospital, aged 57, died, December 27, of myocarditis

Fletcher Kindry White, Sewickley, Pa., Western Reserve University Medical Department, Cleveland 1884, aged 84, died, November 27, in the Sewickley Valley Hospital of bronchopneumonia, arteriosclerosis and senility

Frances Hulbert White, Fairport, N Y, University of Michigan Department of Medicine and Surgery, Ann Arbor, 1896, member of the Medical Society of the State of New York, aged 72, died, January 3, of coronary thrombosis

Walter Walton White Jr, Baltimore, University of Maryland School of Medicine, Baltimore, 1896, served on the staffs of the Church Home and Infirmary, St Joseph's Hospital and the Maryland General Hospital, aged 67, died, January 2, of carcinoma of the spine

Edward Watts Morris Whitehead, Salisbury, N C., University of Pennsylvania School of Medicine, Philadelphia, 1924, had served as director of the old North Carolina Bank and Trust Company, aged 44, died, December 14, of coronary thrombosis

Lanson C Wilson, Hayward, Calif., Eclectic Medical Institute, Cincinnati, 1887, aged 83, died, December 31

Harro Woltmann @ Mansfield, Ohio, University of Michigan Department of Medicine and Surgery, Ann Arbor, 1905, fellow of the American College of Physicians, for many years actively interested in the work of the Richland County Tuberculosis and Health Association, serving as a member of the executive committee and chairman of the program committee of that organization, served as chief of staff, Mansfield General Hospital, aged 60, died December 27, of tuberculosis

James Byron Young @ Indianapolis, Medical College of Indiana, Indianapolis, 1901, served as a captain in the medical corps of the U S Army during World War I, member of the medical section of the American Life Convention and the Association of Life Insurance Medical Directors in 1920 became medical director and in 1934 elected a member of the board of directors of the Indianapolis Life Insurance Company, formerly chief of staff at St Francis Hospital, aged 64, died February 7, in St Vincent's Hospital of coronary occlusion and influenza

Thomas A E Young, Morristown, N Y., Trinity Medical College, Toronto, Ont., Canada, 1897, veteran of the Spanish American War, aged 66, died, January 22, in the A Barton Hepburn Hospital of chronic nephritis

DIED WHILE IN MILITARY SERVICE

Joseph William Mendoza, Pittsburgh, University of Pittsburgh School of Medicine, 1933, called to active duty April 1, 1941 as a captain in the medical corps of the Army of the United States, aged 31, was killed, January 2, in an aircraft accident somewhere near Newfoundland while serving as flight surgeon with the army air corps

Abbott Kenyon Bailey, Acting Assistant Surgeon, Lieutenant junior grade, U S Navy, Portsmouth, Va., Jefferson Medical College of Philadelphia, 1942, an intern at the Norfolk Naval Hospital, aged 25, died December 31, of a self-inflicted bullet wound

Bureau of Investigation

MISBRANDED PRODUCTS

Abstracts of Notices of Judgment Issued by the Food and Drug Administration of the United States Department of Agriculture

[EDITORIAL NOTE—These Notices of Judgment are issued under the Food Drug and Cosmetic Act and in cases in which they refer to drugs and devices they are designated D D N J and foods F N J. The abstracts that follow are given in the briefest possible form: (1) the name of the product, (2) the name of the manufacturer shipper or consigner, (3) the date of shipment, (4) the composition, (5) the type of nostrum, (6) the reason for the charge of misbranding and (7) the date of issuance of the Notice of Judgment—which is considerably later than the date of the seizure of the product and somewhat later than the conclusion of the case by the Food and Drug Administration.]

A Z Tablets—A Z Sales Company Waterbury Conn. Distributors and Strong Cobb and Company Inc. Cleveland shippers. Shipped June 8 1940. Composition essentially potassium acid tartrate calcium gluconate ulnar podophyllum golden seal starch and a small amount of an iron compound. Misbranded because labels and accompanying circular falsely represented the product to be efficacious in treating asthma asthmatic spasms bronchitis catarrh congestion of the upper respiratory system hay fever head colds and nasal irritations.—[D D N J F D C 491 September 1942]

Enrich—Offered for sale by Vita Health Food Company Washington D C. Composition (according to labeling): Each fluid oz contains 600 mg peptonized iron 200 U S P units vitamin B₁ 100 micrograms vitamin B (riboflavin) rice bran extract (which contributes other factors of the vitamin B complex) manganese as the citrate calcium and sodium as the glycerophosphates. Two teaspoons of Enrich 4 times daily furnish 99 milligrams of iron. Two teaspoons of Enrich 4 times daily supply four fifths 80% of the entire day's needs (minimum U S standard). Misbranded because of false and misleading statements on an accompanying placard: New hope for folks over 40. This combination of iron and vitamin B₁ has helped to restore pep and vigor to thousands. If you suffer from low vitality neuritis nervousness or other nerve disorders stomach distress colitis or constipation loss of appetite pale cheeks lips eyelids or gums poor functioning iron poor blood cold hands or feet loss of vigor you may need more of the vital elements iron and vitamin B₁. Enrich benefits your blood nerves glands and every organ of your body if you lack iron and vitamin B₁.—[D D N J F D C 496 September 1942]

Dr. Carey's Marsh Root Prescription 777 Tablets and Dr. Carey's Marsh Root Laxative Pills—Earle Soap Manufacturing Company Baltimore. Shipped Sept. 13 1940. Composition tablets consisted essentially of plant drugs including a laxative and an alkali-bearing drug with methyl salicylate sodium salicylate potassium nitrate sugar starch and talc the pills were composed essentially of plant material including a laxative drug. Both products misbranded because their names falsely represented that they consisted essentially of marsh root whereas both contained therapeutically active ingredients other than this substance. Further misbranded because statements on and in the packages represented that the tablets would be efficacious as a diuretic a stimulant of the kidneys and urinary system and a cure preventive or mitigation of kidney diseases and that the pills would be effective as a tonic that they were gentle as Nature were not habit forming and were of value for sufferers with kidney or bladder troubles.—[D D N J F D C 500 September 1942]

Dr. Shreve's Anti Gall Stone Remedy and Dr. Shreve's S and L Pills—Dr. Shreve's Medicine Company Newton Iowa. Shipped May 11 1940. Composition the first product was a liquid consisting essentially of lime water and a white sediment and was flavored with saffron; the pills contained plant material (including a laxative) and metallic mercury (equivalent to 0.68 grain of mercury with chalk per pill) and were coated with sugar and calcium carbonate. The Anti Gall Stone Remedy was misbranded because of false and misleading representations in the labeling and accompanying circular that it would be efficacious as a gallstone remedy would produce a chemical change in the gall and alter the secretions of the gallbladder liver kidneys and bladder and place the system in a better condition. Dr. Shreve's S and L Pills were misbranded because of false and misleading label representations that they would be efficacious in treating catarrh of the stomach or bowels dizziness nausea diarrhea or dysentery would promote digestion and assimilation restore tone to the system and be effective as a laxative for biliousness and sour stomach.—[D D N J F D C 493 September 1942]

Knox Gelatine—Charles B. Knox Gelatine Company Inc. Johnstown N Y. Shipped between March 20 and April 16 1941. Misbranded because of the following false and misleading claims on package and in accompanying literature: How Knox Gelatine works for you! For endurance. The Knox Gelatine diet is being adopted by men and women all over the country who report that it really works. Hundreds of people who have completed 28 day occupational group tests

have reported that Knox Gelatine has reduced fatigue to a significant degree. This is not theory. It is based upon carefully collected reports of men and women whose work makes strenuous demands on mental and physical endurance. How to take Knox Gelatine for more endurance—less fatigue. The latest research development—and the most widespread—is the use of Knox Gelatine in building endurance and resistance to fatigue. Also misbranded in violation of the provisions of the law applicable to foods is reported in F N J No 2548.—[D D N J F D C 497 September 1942]

No Wheez Cough Syrup—No Wheez Corporation St. Charles Mo. Shipped between March 1 and May 24 1940. Composition essentially small amounts of pine tar menthol an emodin bearing drug chloroform sugar and water. Misbranded because falsely represented in labeling as effective for treating bronchitis whooping cough sore throat and similar conditions and preventing wheezing in these disorders.—[D D N J F D C 489 September 1942]

Parlsian Style Sage—Cironx Manufacturing Company Buffalo. Shipped March 29 1940. Composition essentially water alcohol glycerin and small amounts of resorcinol volatile oils and capsaicum. Misbranded because of false and misleading representation that the product was effective to aid normal hair growth and for helping the natural growth of the hair. Also misbranded under provisions of the law applicable to cosmetics as reported in C N J No 66.—[D D N J F D C 508 September 1942]

Robinson's for Rheumatism Arthritis Neuritis and Lumbago—Albert J. Robinson Allentown Pa. Shipped May 29 1940. Composition essentially potassium iodide (44.8 grams per hundred cubic centimeters) and alcohol (5 per cent). Misbranded because of false and misleading label representations. For rheumatism arthritis neuritis lumbago. A foe to pain and statements in accompanying circular representing that the product would be effective in treating these conditions would lead and re-lead to normally helpless victims of such disorders would bring freedom from pain and distress and effect perfect health regardless of whether the disorder was of recent origin or had developed to a serious stage and would relieve suffering and disability.—[D D N J F D C 491 September 1942]

Tongue River Apries Honey—Tongue River Apries (E. C. Reed & Son) Ranchester Wyo. Shipped Oct. 1 1940. Misbranded because the claims that the product was helpful for impaired digestion diabetes etc. and that a teaspoonful in warm water induces sleep and stimulates the heart were false and misleading since the use of this honey could not be depended on to fulfil such promise. Further misbranded because of false and misleading statements regarding its alleged efficacy in maintaining health treating heart weakness and heart failure and reviving heart action and its alleged value in cases of pneumonia and general physical repair also as to its alleged effectiveness in producing energy and a healthy complexion its purported usefulness as a cosmetic because of its claimed nourishing bleaching astringent and antiseptic effect on the skin. Also misbranded under provisions of the law applicable to foods as reported in F N J 2811.—[D D N J F D C 499 September 1942]

Vitalax Perdz—Manuel Perdz trading as Vitalax Laboratories Buffalo. Shipped May 16 1940. Composition glycerophosphates of sodium and calcium small proportions of iron phosphate zinc phosphide and nux vomica with indications of brewers yeast and extract of cod liver oil all in tablet form and coated with calcium carbonate and pink coloring. Biologic examination showed that it contained approximately 5 international units of vitamin B₁ per tablet. Misbranded because label statements Recommended for tiredness loss of weight irritability and nervousness lack of appetite lack of energy and pale complexion when due to nutritional anemia and secondary anemia and it is recommended for fatigue loss of weight irritability and nervousness lack of appetite lack of energy and pallor of the face and anemia caused by nutritional deficiency were false and misleading since the product would not be efficacious for such purposes. Further misbranded in that the name Vitalax and the claim This exceptional tonic is made of fine ingredients of recognized medicinal value combined with vitamins B and Active ingredients vitamin B. Dose 4 tablets a day were false and misleading since they represented and suggested that the preparation contained a therapeutic amount of vitamin B₁ whereas it did not and because the labeling failed to reveal the fact material in the light of such representations that the recommended total daily dosage 4 tablets would supply less than one thirtieth of the average therapeutic dose of vitamin B₁. Also misbranded because the statement It does not contain any injurious drugs was false and misleading since the product did contain nux vomica and zinc phosphide drugs which might be injurious.—[D D N J F D C 497 September 1942]

Wiel Garlic Tablets—Wiel Laboratories Inc. Brooklyn. Shipped March 2 1940. Composition a small amount of garlic flavored with peppermint and coated with sugar calcium carbonate and a starchy material. Misbranded because labeling falsely represented that the product would build better health stimulate digestion and reduce high blood pressure that garlic causes the relaxation and expansion of the tiny blood vessels and small arteries which have the direct and immediate effect of lowering blood pressure that it would act by stimulating peristaltic movement of the bowels and would rid in dispelling excessive flatulent gas and its disagreeable symptoms of nervous fatigue coated tongue and sleeplessness and that it would relieve that peculiar dizziness and headache which usually accompany high blood pressure and would help to overcome jumpy nerves due to ordinary constipation whereas it would not be efficacious for such purposes.—[D D N J F D C 498 September 1942]

INTRAVASCULAR AGGLUTINATIONS IN AVIAN MALARIA

To the Editor—In the January 23 issue of THE JOURNAL, under Current Comment you reviewed an article by Dr Arthur R Lack on Intravascular Agglutinations in Avian Malaria. In your review you credit to the University of Chicago the original and fundamental observations on circulatory changes in malarial malaria made by Dr Knisely and his co-workers. While your misunderstanding is a normal inference from Dr Lack's paper these observations were made, in fact, by Dr Knisely and his co-workers at the University of Tennessee during a two year period when Dr Knisely was on leave of absence from the University of Chicago.

T P LASH JR PH D, Memphis, Tenn
Dean, University of Tennessee School
of Biological Sciences

To the Editor—In the January 23 issue of THE JOURNAL you review an article by Dr Arthur Lack on the intravascular agglutination of blood in avian malaria. The original observations on the intravascular agglutinations and consequent sludging of the blood were made in *Macacus rhesus* monkeys infected with *Plasmodium knowlesi* malaria. These observations were made in the late summer and fall of 1940 at the University of Tennessee Medical School by Drs Warren Stratman-Thomas, Theodore S Eliot and myself. A preliminary note on this work was published in the *Anatomical Record* (79:90 [March, supp 2] 1941). These studies have been carried on for the past two years at the University of Tennessee through the cooperation of the University of Tennessee, the Tennessee Valley Authority and the University of Chicago. These three institutions pooled facilities, equipment and manpower for the work. In addition to those mentioned Mr Edward H Bloch, Mr Robert Michler, Miss Lois Levy, Miss Louise Warner and, toward the end of the work, Dr Arthur Lack also worked on one or more of the problems involved.

The studies were carried on to learn progressive pathology of *Plasmodium knowlesi* malaria in monkeys, to learn the mechanisms by means of which the sludging of the blood causes symptoms and damage to the body, and to learn the details of the steps whereby the monkey destroys malaria parasites, how the parasite destroying mechanisms operate, how and why they fail, and to learn the effects of antimalarial drugs on these processes. Motion pictures were taken through the microscope of a number of the processes involved. Results of these studies are now being prepared for publication.

Dr Lack was trained in this type of study by the members of our group in order that he might proceed with such studies in other forms of malaria and in other diseases. No harm has been done because his preliminary paper on the sludging of blood in avian malaria has appeared before the publication of the more extensive reports of studies on monkey malaria.

At the end of the editorial comment it is stated, in reference to the intravascular agglutination of the blood in malaria that "the phenomenon presumably occurs in men." A few human patients with malaria have been studied. Every one had the intravascular agglutination. The intravascular agglutination has been seen in human beings with each of the three common species of human malaria. It has also been seen in acute alcoholism and in a variety of other human diseases. A preliminary note on this was published in the *Anatomical Record* (82:426 [No 3] 1942).

Virginia June Report

The Virginia State Board of Medical Examiners reports the written examination for medical licensure held at Richmond in June 1942. The examination covered 8 subjects and included 80 questions. An average of 75 per cent was required to pass. One hundred and thirty-nine candidates were examined, 138 of whom passed and 1 failed. The following schools were represented:

School	PASSED	Year Grad	Number Passed
George Washington University School of Medicine	(1942-3)		3
Howard University College of Medicine	(1941)*		1
Rush Medical College	(1941)		1
University of Chicago The School of Medicine	(1937)		1
Johns Hopkins University School of Medicine	(1942)		1
Washington University School of Medicine	(1942)		1
University of Nebraska College of Medicine	(1937)		1
University of Rochester School of Med and Dentistry	(1939)		1
Hahnemann Medical College and Hospital of Philadelphia	(1942)		1
University of Pennsylvania School of Medicine	(1942)		1
Medical College of Virginia	(1941)	(1942-57)	58
University of Virginia Department of Medicine	(1942-59)		59

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Governmental Hospitals. Validity of Rule Forbidding Performance of Major Surgery Without Presence of a Staff Member.—The Public Hospital of the city of Sterling, Ill. is as its name indicates owned and operated by the city of Sterling. Rules adopted by its board of directors make its facilities available to physicians who are staff members or who are associate staff members provided only that a 'major operation' may not be performed unless either the operating physician is a staff member or there is in attendance, prepared for assistance in the operation, one or more members of the staff in addition to a proper anesthetist. The plaintiff, Selden, an associate staff member sought to enjoin the city and the hospital board from enforcing the rule limiting the right of associate staff members to perform surgery in the hospital. Apparently he based his right to relief on a section of the state statutes under the authority of which the hospital was established and operated by the city, which provides, in part, as follows:

All physicians who are recognized as legal practitioners by the Department of Registration and Education [the state agency issuing all licenses to practice any form of the healing art] shall have equal privileges in treating patients in such a hospital. Ill. Rev. Stat. 1941 C 24 §44.1

The trial court dismissed the bill of complaint for want of equity, and the plaintiff appealed to the appellate court of Illinois, second district.

Another rule of the hospital provided that associate staff members might become staff members on invitation after being recommended by the executive committee of the staff. Selden contended that this rule did not set up a standard capable of ready determination so as to enable a physician to know when he was eligible for staff membership. The apparent contention was that because there was no adequate standard for staff membership the other rule limiting the use of the hospital facilities for the performance of surgical operations was invalid. There is no merit to this contention, said the court. There is a specific hospital rule providing for admission to membership

on the associate staff by application and probation and to membership on the staff on invitation after being recommended by the executive committee. The recommendation of the executive committee is based on the observation of its several members of the applicant's qualifications as to his work and his ethics, and if they are good he is invited to become a member of the staff. What other provision would be necessary to constitute any more definite standards is not suggested. Further more the rules adopted by the board of directors are those of standard hospitals. The rules governing admission to membership on the staff apply to all physicians alike and tend to maintain a high degree of skill and integrity in the membership. It is obvious that rules must be adopted to protect patients in major operations from unethical or unskilled practitioners, even though they are licensed physicians. The rule in controversy is fundamentally a provision for the public safety and the public welfare. It is in no sense for the personal benefit of the hospital or the board of directors except in maintaining the standard of excellence and proficiency contemplated by the statute and required by the welfare of the public. It insures the attendance and, if required, the assistance of a practitioner of experience and ability in case the operating physician should meet with a condition to which he is not equal, so that nothing may be left undone for the benefit of the patient. The section of the statute purporting to accord equal privileges in hospitals operated by cities to all physicians recognized as legal practitioners by the department of registration and education was never intended to prohibit the board of directors of a public hospital from adopting rules that will inure to the benefit of hospital patients. The manifest object of the statute referred to was to prevent discrimination of which there is no evidence in this case. The decree of the circuit court dismissing the complaint was accordingly affirmed.

On a petition for rehearing the plaintiff argued that there was nothing in the rules of the hospital which provides that when a physician has attained a certain high degree of skill, based on a given amount of experience, that he shall then be recommended by the executive committee for membership on the staff. That is true, said the court. It is not possible however, to prescribe by rule a standard of skill dependent on experience. Skillfulness may be, but is not always, brought about by experience. A physician with only limited experience may be a very skilful surgeon while one with many years of experience may be a bungler. The hospital rule here challenged is not in our opinion, an unreasonable rule. It applies alike to all physicians and cannot, on the evidence found in this record, be said to discriminate against the plaintiff. The petition for a rehearing was accordingly denied.—*Selden v. City of Sterling*, 40 N. E. (2d) 329 (Ill., 1942).

Chiropractic Practice Acts. Validity of Law Abolishing Chiropractic Examining Board and Conferring Its Duties on Central Licensing Authority.—Rasmussen was convicted of violating the chiropractic practice act of Washington on an information charging that without being licensed by the director of licenses to practice chiropractic he induced the belief that he was lawfully engaged in that practice. He appealed to the Supreme Court of Washington.

Rasmussen contended that the information on which he was convicted did not charge an offense under the laws of the state. His argument ran somewhat as follows. There is now no valid law limiting the practice of chiropractic to persons licensed to do so by the director of licenses. When the chiropractic practice act was enacted in 1921 it contained a section, which still exists as a law, prohibiting the practice of chiropractic and certain other related acts without complying with provisions of the act. In addition the 1919 enactment contained provisions creating a board of chiropractic examiners with power to examine and license applicants for licenses to practice chiropractic. In 1921 a legislative act (Laws 1921, chapter 7) abolished a large number of administrative boards and agencies among them the board of medical examiners and the board of chiropractic examiners, and vested the rights and duties of the boards and agencies abolished in a few stated agencies. By that law the powers and duties of the chiropractic board, among others, was vested in the director of licenses. The law complained of did not set out in full any of the acts affected by it but merely

referred by name to the agencies abolished. This 1921 law, the defendant argued, was invalid because it was an attempt to amend the preexisting chiropractic practice act without complying with that section of the Washington constitution which provides that "No act shall ever be revised or amended by mere reference to its title, but the act revised or the section amended shall be set forth at full length" (Constitution, article II, section 37). The defendant argued that since the law attempting to give the director of licenses power to license applicants for licenses to practice chiropractic and, in effect, attempting to make it unlawful to practice without a license from the director was invalid, there was no provision by which a person could be licensed to practice chiropractic, and hence he committed no offense in practicing, or inducing a belief that he was engaged in practice, without a license. A statute, said the Supreme Court in answer to this contention, must be sustained and enforced unless it is in clear and irreconcilable conflict with some express provision of the constitution. On the other hand, if the constitutional provision and the legislative enactment are so clearly in conflict that they cannot both stand, the statutory provision must, of course, fail. Provisions similar to the provision in the Washington constitution prohibiting revision or amendment by reference to title alone and requiring the act or section revised or amended to be set out in full are found in most state constitutions and at an early date the courts adopted the rule that a provision of this nature must receive a reasonable interpretation. In *People ex rel Drake v Mahoney*, 13 Mich 481, it was said:

This constitutional provision must receive a reasonable construction with a view to give it effect. The mischief designed to be remedied was the enactment of amendatory statutes in terms so blind that legislators themselves were sometimes deceived in regard to their effect and the public from the difficulty in making the necessary examination and comparison failed to become apprised of the changes made in the laws. An amendatory act which purported only to insert certain words or to substitute one phrase for another in an act or section which was only referred to but not republished was well calculated to mislead the careless as to its effect and was perhaps sometimes drawn in that form for that express purpose. But an act complete in itself is not within the mischief designed to be remedied by this provision and cannot be held to be prohibited by it without violating its plain intent.

Following this rule of reasonable interpretation, continued the court, the courts have designated certain statutes which refer to other statutes as "reference statutes" and not within the restriction contemplated by the constitutional provision. Reference statutes are of frequent use to avoid encumbering the statute books by unnecessary repetition, and, in the absence of constitutional restrictions, they have frequently been recognized as an approved method of legislation. *State ex rel Hunt v Taustick*, 64 Wash 69, 116 P 651.

The 1921 act, continued the court, which among other things abolished the board of chiropractic examiners and conferred its duties on the director of licenses, in no way changed or amended the law pertaining to the qualifications or requirements for chiropractors in this state. It merely abolished the state board of chiropractic examiners and transferred its duties to the director of licenses without in any way changing those duties. Legislatures have frequently passed laws abolishing offices or departments and conferring their duties and functions on newly created offices or departments. These statutes have generally been held to be constitutional under state constitutions similar to that of Washington. For instance, *In re Hadley*, 336 Pa 100, 6 A (2d) 874 the court said:

We have several times held that an act terminating given powers and duties in one agency and transferring them to another agency is not required to republish at length all the acts originally conferring such powers and duties.

The court accordingly held constitutional the 1921 act which abolished the board of chiropractic examiners and conferred its powers on the director of licenses.

The defendant contended next that the trial court committed error in admitting into evidence a telephone directory of the community in which the chiropractor lived in which he was listed as a chiropractor and in refusing to strike the testimony of the manager of the telephone company, who identified the directory, testified that the listing in the directory of the defendant as a chiropractor cost the defendant an additional charge of 50 cents a month, and that such a listing was made only at the request of the person listed and admitted that he per-

sonally had made no contract with the defendant for such listing. An investigator of the state department of licenses testified that he had called at the defendant's home on a stated date and that there was a sign on the porch bearing the legend "X-Ray and HIO Chiropractor," that on the front door was printed the defendant's name and office hours and that the defendant in conversation with him answered "yes" to the question as to whether or not he was practicing chiropractic and showed the witness that he had been admitted in one or two other states. The defendant contended that it was necessary for the state to prove that the insertions in the telephone directory were placed there at his request. It does not appear, said the court, that there was any direct evidence available regarding the insertion of the defendant's name in the telephone directory. However, circumstantial evidence was admissible to prove that fact and the testimony of the manager of the telephone company relative to the contents of the telephone directory and the directory itself were admissible in evidence when considered in connection with the testimony of the investigator from the department of licenses. The conclusion of the court in this regard found support in *State v Bennett*, 6 Wash (2d) 208, 107 P (2d) 344. In that case the defendant was convicted of the same offense as the defendant here. The only evidence introduced was that of two inspectors of the state department of licenses to the effect that the defendant's office had on the window the words "Palmer Graduate, X-Ray, Chiropractic", that on entering the office they found cards with the defendant's name and telephone number thereon, and that the defendant admitted that he was practicing. A telephone directory listing the defendant as a chiropractor was also received. There the court said:

We are of the view that upon the evidence the jury not only could have believed that appellant was engaged in the practice of chiropractic without having a license so to do but also was clearly warranted in finding as it did that appellant had induced a belief on the part of the general public that he was engaged in that profession.

It is true as appellant points out that the inspectors did not see the appellant actually performing any manual operation upon a patient and that no witness testified that he or she had been induced to believe that appellant was engaged in the practice of chiropractic. However it was not essential that the charge of inducing belief be established by direct evidence. A criminal case like any other may be proved by circumstantial evidence and reasonable inferences have the same probative effect as direct testimony.

It is a well settled rule of evidence that any inference which may be reasonably drawn from a fact testified to by a witness is as legitimate evidence as the fact itself.

The conviction of the chiropractor was accordingly affirmed.—*State v Rasmussen*, 128 P (2d) 318 (Wash., 1942).

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1932 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

Hypertension and Cardiac Rupture.—Among 25,000 consecutive necropsies performed during seventeen years the hearts of 865 (3.4 per cent) had one or more unhealed infarcts. Edmondson and Hoxie state that among these 865 there were 72 with ruptured hearts; the ruptured hearts of only 19 (26.3 per cent) contained scars as compared to 58.4 per cent of those with unruptured hearts and unhealed infarcts. The 33 and 36 per cent incidence of rupture in the seventh and eighth decades closely paralleled the 33 and 28 per cent incidence of infarction in these decades. The difference shown in the eighth decade is not statistically significant. Of the 865 patients 601 were males and of the 72 with ruptured hearts only 40 were males. The seasonal incidence of rupture of the heart did not differ significantly from that of myocardial infarction and the frequency of obesity was practically the same in these two groups. In the ruptured hearts the infarcts tended to be smaller more completely necrotic and more heavily infiltrated with polymorphonuclear leukocytes. Of 100 consecutive patients whose nonfatal myocardial infarction was determined on convincing clinical and electrocardiographic evidence, 23 had a blood pressure of or above 140 systolic and 90 diastolic, the average was 125/78. Of 657 patients who had myocardial infarction that terminated fatally without rupture, 210 had a blood pressure of or above 140/90; the average being 128/81. In 39 of 62 patients who died of cardiac rupture the blood pressure was 140/90 and the average 148/90. The average calculated time between infarction and rupture was seven and four tenths days, 98 per cent occurred on or before the sixteenth day after infarction and 78 per cent between the third and twelfth days. Only 4 per cent of 368 patients whose hearts weighed 400 or more Gm and who had a blood pressure of less than 140/90 after infarction had cardiac rupture as compared to 25 per cent of the 28 whose hearts weighed less than 400 Gm and whose blood pressure was higher than 140/90.

Syphilitic Coronary Stenosis with Myocardial Infarction.—Three patients with myocardial infarction secondary to syphilitic coronary thrombosis were found by Burch and Winsor in their review of the protocols of 6,225 consecutive necropsies at the Charity Hospital during the last five years. These 3 patients comprised 1.6 per cent of all cases of myocardial infarction. Nine similar cases are reported in the literature. The average age of the patients with syphilitic coronary stenosis was 45 years. Both arteries were usually involved. The white to Negro ratio was about 1.6 and the female to male ratio about 1.35. The blood Wassermann reaction was positive in 96.3 per cent. The average weight of the hearts with coronary stenosis alone was 413 Gm, whereas the average weight of the hearts of patients who had had coronary stenosis and aortic regurgitation, hypertension or both was 680 Gm.

Papaverine and Circulation Time.—Elek and Solari noticed a sudden, almost uniform deepening of respiration shortly after injection of papaverine hydrochloride. They adopted the following technique. The patient lies supine in a quiet room for at least five minutes before the test is performed. He is informed as to what will probably occur and is asked not to cough, sigh or take a voluntarily deep breath. The ante-cubital vein is used for injection and the arm is so placed on a pillow that the level of the site of injection will be about 10 cm above the posterior axillary line. About ten seconds are allowed to elapse between insertion of the needle and injection of the drug through a 2 cc. I.V. syringe and a 20 gage needle. The papaverine hydrochloride, 40 mg. is injected within one second and the circulation time is clocked. The end point is signaled by a sudden, deep inspiration, with employment of the abdominal muscles, which interrupts the usual phase of respiration and is at times accompanied by a sigh or gentle exclamation. This is commonly followed by flushing of the face or cheeks, a feeling of facial warmth, a sensation of throbbing in the temples, mild dizziness and less frequently, acceleration of the heart. The tachycardia lasts fifteen to sixty seconds with an average of about thirty seconds. The range of values for the circulation time with papaverine for 41 men and 9 women without subjective or objective signs of heart failure varied from fifteen and four tenths to twenty seven seconds, the average was twenty and eight tenths seconds. Duplicate measurements were done of 24 at intervals of two to five minutes, the range of differences between any two measurements was zero to three seconds and the average was one and two tenths seconds. The data on 6 patients with congestive heart failure and 4 with hyperthyroidism show that in those with heart failure the papaverine circulation time, as the sodium dehydrocholate time, was definitely prolonged. The papaverine circulation time in hyperthyroidism was shortened, but the deviation from normal was not as definite as its prolongation in heart failure. Indirect evidence suggests that papaverine hydrochloride may measure the arm respiratory center circulation time.

Latent Primary Carcinoma.—Gewanter and his collaborators report 25 cases of latent primary cancer encountered among 2,514 necropsies (391 were of cancer) between November 1935 and January 1941 at the Queens General Hospital. It is suggested that the term "latency" be used only for cancer which

produces symptomatic precocious metastasis while it itself remains silent. Symptoms due to the primary involvement were present before death in only 3 of the patients. In 8 instances the primary site was not established at necropsy and in 2 there were double primary tumors. The latent primary cancers were found at nine separate sites: lung, stomach, pancreas, prostate, fundus, uteri, testis, male breast and ovary. In 2 the site could not be determined. The site of the precocious metastasis was the central nervous system: long bones, peritoneum, pleura, lung, liver, lymph nodes, intestine, ovary and adrenal. Metastasis in the central nervous system occasioned manifestation of obstructive hydrocephalus, hemiplegia, the cerebellar syndrome, increased intracranial pressure due to an expanding lesion and paraplegia associated with extradural spinal involvement. Bone involvement was evidenced by pain or pathologic fracture. Involvement of the peritoneum and pleura usually caused effusion, with pain or intestinal obstruction. The latency of any cancer is determined by its biologic growth processes, by its site and by chance. The location of metastasis will of itself condition the early or late appearance of clinical symptoms. The proximity of a tumor to large vascular structures will be determinative of metastatic symptoms as compared with a similar lesion in the periphery of a relatively avascular organ. Some inherent biologic properties of individual neoplasms may play a determining role in their latency.

- *A New Disease Entity (?) C D Bowdoin Atlanta—p 437
A New Disease Entity?—Bowdoin reports the occurrence during August 1940 at Wiens Ga, of an outbreak of 35 cases of an unusual disease. The first patient became ill on August 1 and by August 21 the 35 patients had recovered or were recovering. The county health department made a study of 17. The

patients were males between 6 and 42 years of age and gave a history of sudden onset with severe predominantly frontal headache, postorbital pain, chilliness and sweating. About two thirds of the patients complained of nausea and many vomited. About two thirds complained of lumbar pain and pain in the legs, and one third complained of some pain in the joints. Epigastric pain was complained of by about one half of the patients and diarrhea by 2, but constipation was the rule. The most striking feature was a fine red rash chiefly over the anterior aspects of the legs; it was more predominant over the tibia. The rash was finer but not unlike that seen in measles. It remained only twenty-four to forty-eight hours and usually appeared around the fifth day. The acutely ill patients presented a rather dull facies with slight to moderate injection of the conjunctivas and some slight injection of the throat. The temperature ranged from 100.6 to 104.5 F and was accompanied by a pulse between 55 and 90. The only common etiologic factor was a small sluggish, little stream which pooled into an old swimming hole. Every patient had found relief from the summer heat in this dirty swimming hole. One technician was assigned to handle stool cultures and she became ill in about ten days. The author is convinced that she had a laboratory (secondary) infection of the same disease. Agglutination tests done on the convalescent serums of 22 patients, including the technician, were negative. Since bathing in the particular swimming hole was the only common factor, water transmission must be considered. It would appear that the disease is an entity probably due to an unknown causative agent, but the infection in the laboratory technician suggests its presence in the stool.

Irradiation and Air Borne Infection—Sommer and Stokes found that irradiation in an experimental ward had some beneficial effect on the air of a nonirradiated control ward because of an open corridor between the two wards. The irradiation reduced the number of air borne organisms in both the irradiated and the nonirradiated ward. It also may have

influenced the kinds of air borne organisms and the number of subclinical and clinical hospital infections. There was a suggestive reduction of pneumococcal cross infections contracted in the irradiated and in the control ward.

Irradiation, Propylene Glycol Evaporation and Air Borne Infection—The scanty data obtained in a clinical study prompted Henle Sommer and Stokes to use mice in determining the effect of ultraviolet irradiation and propylene glycol vaporization on air artificially contaminated with droplet nuclei derived from cultures of hemolytic streptococci of Lane field's group C or the virus of influenza A and on cross infection in the animals. Groups of animals were placed in some cubicles while the cultures were atomized in one of the cubicles of a ward. Both organisms spread rapidly throughout the air of the ward. With heavy concentrations of more than 3000 of air borne streptococci per cubic foot of air most control mice died while propylene glycol vapor protected them completely and ultraviolet irradiation failed to prevent death only among the animals in the cubicle containing the atomizer. With low concentrations of the streptococcus (200 to 500 organisms per cubic foot) all mice survived and cultures from the lungs on the eighth or tenth day failed to reveal the streptococcus. However a carrier state was induced in the control animals but not in those protected by ultraviolet light barriers. Ultraviolet irradiation and propylene glycol vapor were similarly effective in preventing air borne infection with the virus of influenza A. All control mice died propylene glycol vapor protected the animals completely as did ultraviolet irradiation with the exception of a few mice in the cubicle containing the atomizer. Droplet and possibly dust borne infection may require different means of control.

Severe Infections in Infants and Children—Since the first case of meningitis was treated with sulfonamides in the St. Louis Children's Hospital 100 patients have been admitted with signs and symptoms sufficiently suggestive of bacterial meningitis. Hartmann and his co workers review the 12 among the group with acute hemolytic streptococcus meningitis. The infection almost invariably is a complication of acute or neglected infection in the upper part of the respiratory tract and usually in the temporal bone. In 3 fatal cases of the series and in 26 others the involvement of the meninges was usually the result of direct extension of the infection from the middle or inner ear, the mastoid or petrous portion of the temporal bone or from the pericardial veins in the carotid sheath. In the fourth patient who died postmortem examination revealed a generalized purulent leptomeningitis, an acute inflammatory process in the left mastoid antrum and bronchopneumonia of the right lower lobe. Complete recovery with little or no residua in 8 of the 12 patients is attributed to both early and accurate diagnosis, the administration of adequate amounts of sulfonamide, adequate supportive treatment of all types and to surgical drainage of accessible suppuration within the temporal bone. No chemotherapy had been employed in 2 of 3 patients who died until they were admitted to the hospital in a moribund condition. In the third patient it is questionable whether the amount administered was adequate, spinal fluid concentrations never exceeded 15 mg per hundred cubic centimeters.

*Use of Ether in Oil Intramuscularly in Treatment of Bronchial Asthma A I Macler Winchester Mass—p 985
The Sulfonamides Their Mode of Action and Pharmacology C A Janeway Boston—p 989

Ether in Oil for Bronchial Asthma—Macler administered intramuscular injections of ether in oil to 11 patients with bronchial asthma. Much more clinical investigation is required for proper evaluation. Of the three types of asthma—acute bronchial asthma, chronic bronchial asthma and status asthmaticus—the first is the least important because, in an uncomplicated case, the symptoms generally respond to the usual medications. However, for the patient who responds favorably but not completely and in whom palliative medication must be continued for several days until relief is obtained an intramuscular injection of ether in oil repeated in four to six or twelve hours if necessary appears not only to aid the symptoms but also to render ephedrine and ephedrine more efficacious. Of 6 patients who had an attack of acute asthma from two to five days and who responded fairly but not satisfactorily to injections of ephedrine, ephedrine sulfate, aminophylline and phenobarbital, 4 received one intramuscular injection of ether in oil and 2 received two injections and within two hours their asthmatic symptoms were controlled. The patients became quieter, were able to breathe more easily and expectorated more freely. Of the 3 patients with chronic bronchial asthma, often for as long as thirty or forty years, the intramuscular administration of ether in oil rendered expectoration much easier, the patients became more comfortable and as the mucus and cough diminished, they may become symptom free unless secondary changes (emphysema and bronchiectasis) or a fresh episode is encountered. The beneficial results may last for several months or longer. The dose is one or sometimes two injections a week and may be continued in conjunction with other approved treatment until the cough, wheezing and sputum are reduced to a minimum. Ether in oil intramuscularly is an adjunct to other therapeutic agents. Of the 2 patients with status asthmaticus so treated, 1 received nine and 1 eleven injections and although they had chronic asthma and had never been completely free of their symptoms, 1 has remained symptom free for more than four and 1 for more than six months.

Northwest Medicine, Seattle

41 401 432 (Dec) 1942

- *Silicosis: General Considerations and Survey in Coeur d'Alene Mining District of Idaho P M Ellis M T Smith H I Bonebrake and J B Hunter Wallace Idaho—p 406
Surgery of Colon H B Stone Baltimore—p 412
Lower Back Headache: Symptoms and Treatment M Gurling Longview Wash—p 419
Actinomycosis of Lung, Minimal Infection H S Atwood Fort George Wright Wash—p 419

Silicosis—Beginning in 1935, one of the mining companies of the Coeur d'Alene region in Idaho started routine physical examinations of new employees and also examined those already working in the mine. In 1936 and 1937 most of the larger companies joined in this policy. Approximately 10,000 examinations were made by the Coeur d'Alene staff. Ellis and his co workers tabulate 7,542 of the examinations. According to the histories, 1,299 had not been exposed to silica dust and 6,243 had been exposed for one to forty five years. Of these 6,243 workers 31 per cent exposed for (an average) three and a half years had no silicosis on roentgen and clinical study, the roentgenograms of 32 per cent exposed for six and twenty nine hundredths years showed excessive linear exaggerations (called presilicosis by many) 232 per cent exposed for more than eight and up to more than fifteen years had silicosis and tuberculosis, 024 per cent exposed for three years had tuberculosis without silicosis and the remaining 35 per cent exposed for eleven to nineteen and a half years had various grades of silicosis. The authors feel that disability from simple uncomplicated silicosis is not as severe as might be assumed from the roentgenograms alone. For determining disability exercise tests such as used

in life insurance examinations and those now used in examining draftees for the Army are sufficient for the average person when a careful history, physical examination and adequate roentgenograms are had. Superimposed infection is the greatest factor in increasing dyspnea, cough and disability to work. Tuberculosis is the most important; it tends to increase the susceptibility to silicosis. Diseases incident to advancing age must be considered. In many persons the treatment of silicosis is entirely that of prevention, and this is an engineering problem. Above all, the contact of the silicotic patient with tuberculosis must be avoided. A man who has worked long enough under present conditions for silicosis to develop is an experienced and valuable employee, especially in these times and he may be able to produce much more, if there is no superimposed infection, than an individual in perfect health with no experience. If this man's exposure to fine quartz particles is low enough to be safe, he in the light of present knowledge, may work productively with little further danger.

Pulmonary Abscess and Aseptic Pulmonary Infarction
—Chester and Krause saw 11 cases of pulmonary abscess secondary to aseptic hemorrhagic pulmonary infarction. In some of the cases the symptoms and signs of pulmonary abscess so dominated the clinical picture that the underlying infarct was not suspected until it was disclosed at necropsy. Some or all of the usual signs and symptoms of pulmonary infarction (hemoptysis, chest pain, dyspnea, pleural friction rub and signs of consolidation) were present in every case in which a pulmonary abscess eventually developed. The distinguishing clinical feature was the occurrence of a foul purulent sputum some days or weeks after the onset of the infarct. It was usually accompanied by a secondary rise in temperature and an elevated leukocyte count. Patients with heart disease had an increase in the severity of the condition. The observations of previous authors as to the roentgen appearance of the infarct shadow have been confirmed. Roentgenologically the infarcts varied widely in appearance, depending on size, position, age and the presence of secondary infection, pleural effusion or passive hyperemia. The typical triangular appearance of the infarct seen at postmortem study was not demonstrated on the roentgenogram unless the central ray passed through the infarct at right angles to its long axis. (If oblique and lateral views are made this triangular shape will be seen more often.) In all cases the infarct became the site of the abscess. If the patient was first seen after the abscess had formed the secondary infection completely masked the underlying infarct. It is therefore important to consider the possibility of an infarct as the underlying cause of all pulmonary abscesses, especially if cardiac failure is present. When the patient was seen early in the course of his disease and serial roentgenograms were made the diagnosis of pulmonary abscess secondary to an infarct was relatively easy. Blood stream infection was excluded from the study so that the infarct of the patients can be presumed to have been aseptic at the time of onset.

Mechanism of Action of X-Ray Therapy on Infection
—Bisgard and his colleagues state that their experimental studies indicate that in rabbits roentgen irradiation is followed by a significant and consistent reduction in the mortality from toxemia of bacterial origin and that this effect is produced by the liberation of an antitoxic factor. Inadvertently, studies designed to investigate certain aspects of peritonitis became a study of toxemia of bacterial origin and of the effect on it of roentgen rays. If a substance which neutralizes or minimizes the effect of toxins can be termed an antitoxic substance, then roentgen rays produced an antitoxic substance in the rabbits used in the experiments. Since this antitoxic factor was present in the blood stream, the protection from irradiation cannot be attributed to local factors inherent in the treated tissues such as hyperemia, increased or decreased permeability of the capillaries or lymphocytic infiltration as suggested in the literature. The following theory is offered to explain the results. Roentgen rays are destructive agents. In response to this insult the cells, or some group of cells, liberate a protective or antitoxic factor. This protective reaction to injury may be not unlike that evoked by various chemical agents such as snake venom and even bacterial toxins. Time is required for the protective mechanism to develop. In the authors' experiments it was present twenty-four hours after irradiation. Protection apparently developed too slowly to be of benefit to the rabbits irradiated after inoculation. It reached its peak of effectiveness in forty-eight hours and by the seventh day it was apparently entirely dissipated. Harvey, Meloney and Rennie reviewed the reported investigative efforts to establish peritoneal immunity and found that chemical irritants, such as aleuronat and starch mixtures are essentially as effective as vaccines, bacteriogens and serums in producing nonspecific immunity and that the more irritative the agent the greater the immunity. In this category the present authors believe that roentgen rays may be included as a physical agent of irritation and destruction. Porges has suggested that the source of the antitoxic agents of irradiation is the antibodies, ferments and other protective substances which are liberated from the leukocytes that are destroyed by the rays.

Presacral Neurectomy—Dysmenorrhea may be secondary to obvious pelvic disease. Painful menstruation is an exaggeration of the physiologic vasoconstriction of pain-bearing nerves. Rutherford performed a presacral neurectomy on 23 patients in 1939 on 20 for primary dysmenorrhea and on 3 for endometriosis with its secondary or acquired dysmenorrhea. A two year follow-up has been completed for the 23 patients and 8 of them have undergone pregnancy. Labor was normal in 7, while in 1, because of pelvic disproportion cesarean section was necessary. Corrective procedures were combined with presacral neurectomy whenever indicated. In only 1 of the 23 was the result not worth while, pain was relieved 100 per cent in 12, 75 per cent in 7 and 50 per cent in 4.

Sulfonamides for Infected Bone Injuries.—The Heggies and Kendall used sulfapyridine and sulfathiazole, in addition to the standard antiseptic and surgical measures, in the treatment of compound fractures caused by bomb splinters and other high velocity particles and chiefly infected with *Staphylococcus pyogenes*. From their observations they conclude that chemotherapy is a necessary supplement to the surgical treatment of these wounds. Sulfathiazole is more efficacious than sulfapyridine for these staphylococcal infections when the necessary blood concentration is obtained by oral or intramuscular administration. In established staphylococcal infection in bone combined oral and local administration of sulfathiazole at the time of surgical intervention, especially during radical surgical treatment is efficacious. Sulfathiazole applied locally alone and unsupported by simultaneous oral administration is of value in slight or moderate staphylococcal infection even after the bulk of the infected focus has been removed surgically.

Syndrome of Hemorrhagic Adrenal Infarction.—The Keeles believe that the diagnosis of primary hemorrhagic infarction of the adrenals rests on the character of the pain, the severity of vomiting and the absence of 'shock'. In the patient (the senior author) whose history is reported the syndrome was produced by thrombosis of the adrenal vein with resulting hemorrhagic infarction of the adrenal gland. Other causes of hemorrhage into the adrenal are birth trauma in the newborn, meningococcal and other acute infections and as a part of a general hemorrhagic state. The pain, which at first was a 'stitch' and then a cramp was gradual in onset and was accompanied by a feeling of coldness. It was localized (by tenderness) to a point to the right of the umbilicus. It was at first mild but steadily increased until it was of great severity. The pain was persistent and intractable to medication and was aggravated by any movement such as walking. The persistent and

repeated vomiting continued until operation. The operation had no effect on the pain. There was hyperalgesia of the skin in the tender region. Vomiting was the symptom which obscured diagnosis. It started about three hours from the onset of pain, it was copious without retching, almost projectile in character and repeated. There appeared to be little nausea between, when fluids were well taken. Dehydration was not pronounced. Its character and persistence suggested intestinal obstruction. The absence of 'shock' was contrary to expectations in a patient with adrenal disease. This clinical picture is confirmed when an analysis is made of the 10 available clinical records of similar cases. Exploratory laparotomy was performed in 4 of the 10 cases and in none was the diagnosis made. Thus, in the author's opinion, the most important feature of all. If at an exploratory laparotomy the usual sites of acute abdominal conditions are normal, the adrenals should be examined for infarction. The cause of the death of the senior author was diffuse bilateral pulmonary hemorrhage, in the other patients it presumably was renal insufficiency. In cases of Friedrichsen-Waterhouse syndrome pulmonary congestion is commonly mentioned and in view of the present case it would seem that adrenal insufficiency does produce some change in pulmonary circulation.

Vitamin C and Repair of Injured Tissue.—Since it is most important to secure rapid repair of war injuries Bourne presents the available information on the value of vitamin C in accelerating the repair of injured tissue. In 1923 Ishido found considerable delay in the healing of experimental wounds in scorbutic guinea pigs. Work by others has shown that not only is the growth and migration of fibroblasts affected in healing wounds in vitamin C deficiency but phagocytosis also inhibited. In the first stages of the repair of bone cellular proliferation and production of fibers similar to collagen fibers are essential preliminary processes to calcification and therefore a deficiency of vitamin C would delay healing in bone. The changes in scorbutic animals have proved that the healing of fractures would be delayed in scurvy. In general, absorption of the fracture hematoma is delayed, fibroblast activity is reduced and the production of collagen is deficient. Bourne has shown that optimal formation of bony trabeculae in injured femurs of guinea pigs is brought about by the daily administration of 2 mg of vitamin C (probably equivalent to about 40 mg for a human being) and that anything less than 1 mg seriously retards the formation. Healing of a fractured bone calls for more vitamin C than the animal (guinea pigs and rabbits) is able to manufacture. If calcium ascorbate is injected into rats it accelerates the healing of holes previously bored in their femurs. Calcium gluconate was ineffective. To some extent this can probably be explained by the greater ionization of the ascorbate, which is presumably more effective in absorbing calcium from the subcutaneous tissues and possibly by its greater protein combining power. The double bond structure of ascorbic acid is retained in calcium ascorbate and therefore this substance is an antiscorbutic as well as a source of calcium. Deficiency of vitamin C inhibits the deposition of calcium in bones and in guinea pigs receiving daily injections of 2 mg of sodium alizarin sulfonate repair tissue stained strongly in those receiving 0.5 mg it stained less intensely and not at all in those receiving no vitamin C. The work of Gould and Shwachman suggests that vitamin C may play some part in the deposition of calcium by means of its effect on the phosphatase system of bone. Therefore vitamin C in the regeneration of bone may promote the activity of the fibroblast cells and possibly their differentiation into osteoblasts, it may favor the attachment of the polypeptide chains to one another and it may aid in the precipitation of bone salts by its promotion of phosphatase activity. The clinical trial of calcium ascorbate for the treatment of fractures has not yet been tried.

Infected Burns in Naval Personnel—Of 30 patients severely burned with cordite and other high temperature flash burns, the Heggies state that 20 were treated with tannic acid spray and for 10 this therapy proved inadequate so dressings of cod liver oil were used. On admission 8 of the 20 were not infected, 4 were moderately infected and 8 were grossly infected, and, of the 10, 5 were moderately and 5 were grossly infected. With infection the marginal tin loosens. Usually infection occurred from the marginal skin as a result of inadequate antiseptic measures. *Staphylococcus pyogenes* was the predominant organism. In a study of the fauces, skin and clothes of healthy personnel float the organism was found respectively in 20, 25 and 14 per cent, and hemolytic streptococci only in 5 per cent of the fauces. *Staph. pyogenes* was recovered from the burn in all cases of infection. Other organisms recovered were the nonhemolytic streptococcus, *Proteus vulgaris* and *Bacillus subtilis*. Chief among the causes for infection were inadequate initial tanning and antiseptic measures—in short inadequate first aid and next immediate treatment. Antiseptics should never replace surgical cleanliness, but some antiseptic must necessarily be applied to avert infection. Cleansing with spirit soap followed by sterile saline solution and then ether is insufficient and adds to shock by increasing loss of body heat. One of the nonirritant synthetic detergents, in aqueous solution, should replace the relatively inefficient commonly used soaps. Infection was not the only factor that delayed healing. Other factors were deeply affected tissue, too frequent changing of dressings initial or continued protein loss, slow recovery from anemia and the like. When infection cleared up the healing time was similar in the oil and the tan treated patients.

Chronic Pulmonary Infiltration with Eosinophilia—Kartagener points out that transient pulmonary infiltrations with eosinophils, which Löffler differentiated in 1931, have been verified by many investigators. The etiology has not been entirely clarified, probably because there is no uniform cause. The roentgenologic and physical signs and the eosinophilia are transient. The maximum eosinophilia usually appears a few days after the maximum roentgenologic changes. Earlier assumption that edema or atelectasis is the underlying anatomic change have been superseded by von Meyenburg's investigations. This author maintains that these infiltrations represent eosinophilic pneumonia. Transient infiltrations with eosinophils should be designated as eosinophilic infiltration of type Löffler. This type represents an acute process, but the degree of severity of the symptoms is no index of its acuity. The form described by Lohr and by Leon-Kindberg differs from Löffler's type in that the acute symptoms are severe, almost like those of a septic process, and that the process is extremely protracted, it persists for months. Kartagener describes a case which he regards as representative of a third type of eosinophilic infiltration. This form is characterized by chronicity and mildness of the symptoms. The patient, a woman aged 40, had never been seriously ill except for severe gonorrhea. She had never had asthma or bronchitis. She complained of indefinite back and chest pains. Examination demonstrated small foci of infiltration in the right upper lung field, which remained unchanged during fifteen months of observation. The increase in eosinophils persisted with great fluctuations. There were no signs of serious illness aside from intermittent subfebrile temperatures, nocturnal sweats and headaches. She was able to continue her work. Nothing definite can be said about the pathogenesis and etiology of her disorder. Constitutional eosino-

philia can be excluded, but the repeated demonstration of eosinophils in the sputum indicates a relationship between the blood eosinophilia and the pulmonary changes, particularly since asthma can be ruled out. Hodgkin's disease and echinococcus can be ruled out. A tuberculous infiltration cannot be definitely excluded, but in view of the considerable eosinophilia it must be regarded as unusual. Whether the three types of eosinophilic infiltrations represent three variants of the same disease or whether they are distinct entities is difficult to decide. The author suggests that allergic factors might be involved.

Sterilization of Marriage Partners—The Reimann-Hunzikers discuss social or economic indications for sterilization of marriage partners. They stress that the two partners have the same rights and that the question arises which of the two should be sterilized. Since vasectomy in men is a less serious operation than tubal sterilization in women, sterilization of the male is preferable. The authors cite the following as reasons why, as a rule it is the woman who is being sterilized. 1 Historical development of the sterilization of women. 2 Obscure presentation of the indication for the sterilization the social indication is obscured by a fictitious medical indication. 3 The woman, who is directly responsible for the raising of the children, is usually more willing to undergo sterilization than the man. The authors made inquiries in the larger hospitals of Switzerland in order to determine the relative numbers of men and of women who were sterilized for economic reasons. The inquiry reveals a predominance of women. The authors inquired as to the late results with 12 men who had been subjected to a vasectomy at the Basel clinic. It was possible to examine 8 of these from one to six years after the operation. The men had no disturbances and were satisfied with the results. Roulet and Andina made microscopic studies of testes obtained by castration five years after vasectomy, they observed no secondary degenerative changes. There is a possibility of a successful restorative intervention on the vas deferens.

Sudden Death in Starvation—De Salamanca observed a number of sudden deaths in starved persons who had eaten their first food after hospitalization with unusual voracity. Tachycardia and increase in the pulmonary artery tonus may be brought about by excitation of the stomach. The simultaneous stimulation of the vagus and the sympathetic may cause ventricular fibrillation, particularly in the presence of an already impaired ventricle. It is probable that overfilling of the stomach produces a vagosympathetic stimulation in an already defective heart and that this reflex mechanism causes ventricular fibrillation and sudden death. Another possible mechanism is that of an impaired liver not capable of absorbing certain products of digestion and with resulting hemoclastic shock. These causes or a combination of several of them may be responsible for the sudden death in the starved.

Local Sulfanilamide in Trachoma—Morate resorted to various sulfonamide compounds in the treatment of 18 cases of trachoma in children and adults. The drug was well tolerated by the conjunctiva and the cornea. The subjective symptoms rapidly disappeared regardless of the clinical form and duration of the disease. The therapy is simple, economic, painless, clean and hygienic. It resulted in a cure in 33 per cent of the cases and in amelioration of symptoms and in prevention of complications in the rest.

Book Notices

Blood Substitutes and Blood Transfusion Edited by Stuart Mudd, M.A., M.D., Professor of Bacteriology, University of Pennsylvania School of Medicine, Philadelphia, and William Thalheimer, M.D., Director, Human Serum Division, Public Health Research Institute of the City of New York, Inc. Fabrikoid, Price \$5. Pp. 407, with 94 illustrations. Springfield, Illinois & Baltimore: Charles C. Thomas, 1942.

This symposium-monograph contains contributions from seventy collaborating investigators under the editorship of Drs. Mudd and Thalheimer. The discussions concern thoroughly established facts as well as many aspects of blood substitutes and blood transfusion still controversial in nature. The first four chapters discuss the etiology and mechanism of traumatic shock, indeed, the word "shock" might have been included in the title. The contributions are uniformly of high quality even when discussing subjects on the borderline of present knowledge. The arrangement is satisfactory: a section on methods of preservation of plasma and serum by desiccation and by freezing follows the section on shock. The four other divisions are on hemoglobin, serum albumin and casein digest as blood substitutes, blood substitutes in the world emergency, whole blood storage, transportation administration, including isoagglutinins and blood group specific substances, and therapeutic experiences with serum and plasma. The symposium is briefly summarized by Dr. Mudd in a chapter entitled "Recapitulation and Outlook." Concentrated research is rapidly adding to knowledge in the field of blood substitutes and blood transfusion, so that some of the material in this book is already dated. This symposium monograph is a valuable and timely contribution in a vital field.

Microbiology of Meats By L. B. Jensen, A.B., M.Sc., Ph.D., Chief Bacteriologist, Swift & Company, Chicago. Cloth, Price \$4. Pp. 252. Champaign, Ill.: Garrard Press, 1942.

The author has done extensive research in the field of bacteriology of meats and this book contains the results of much of his own research. The introduction and history in chapter 1 covers in a scholarly manner much interesting material from ancient times. The chapter on the gaseous fermentation in meat products by the genus *Bacillus* shows that these bacteria are capable of producing gas in meat containing sodium nitrate. Thiamine is a necessary, although incomplete, factor when meat is excluded. The chapter on green discolorations in meats gives a discussion of the action of oxidizing and sulfide producing bacteria in blood pigments. The chapter on ham souring shows how anaerobic bacteria entering the stick wound during slaughter cause spoilage of hams during curing. The chapter on bacon emphasizes the use of tongs in handling sliced bacon in order to reduce mold contamination. There is an adequate discussion on the control of micro-organisms in the packing plant.

The author has done well in discussing the controversial subject of the use of sodium nitrate in meat. Many will not agree with him that sodium nitrate produces aerobic conditions so that anaerobes such as *Clostridium botulinum* will not grow. McLeod's theory that anaerobes are killed by hydrogen peroxide, which is produced when these organisms are exposed to air, is not so generally accepted. Recent work indicates that oxygen acts indirectly by destroying the reducing potential. If the reducing tension is maintained, anaerobes are able to use measurable quantities of oxygen in their metabolism.

The discussion of the role of microbial oxidase and lipase in the rancidity of fats is ably discussed. Certain minor discrepancies were noted. The author says that bacteria growing on coconut oil agar with Nile blue sulfate as an indicator produce blue colonies when lipase is present. Knaysi, who has investigated the inhibition of growth produced by this dye, contends that the lipase diffusing into the medium coats the fat globules with soap which is colored blue by the dye. The unaltered fat globules remain red. The author believes that the dual acting bacteria producing both lipase and oxidase are responsible for the rapid lypolysis and rancidity in fats. Many readers will not agree completely, remembering that oxidative rancidity by bacteria is mainly a surface effect. Deep in the fat, where intense reducing conditions prevail, destruction of antioxidants will accelerate fat spoilage after the fat is processed and exposed to oxygen.

As in all new books, errors of omission and commission occur. For example, the first chapter on bacterial food poisoning contains, on page 231, an outline for analysis of samples. Directions for growing staphylococci on semisolid mediums in 20 per cent carbon dioxide are not given, although this point is mentioned on succeeding pages in a discussion of the relative merits of various methods of animal testing for enterotoxin. On page 234 is a statement attributed to Dack and Kelley "that bread in sandwiches had been found to be toxic but the filler of the sandwich was nonpoisonous." The filler was toxic. A number of mistakes were also noted in the bibliography.

Text Book of Pharmacognosy By Heber W. Youngken, A.M., Ph.D., Ph.D., Professor of Pharmacognosy and Biology in the Massachusetts College of Pharmacy, Boston. Fifth edition. Cloth, Price \$7.50. Pp. 1,038, with 511 illustrations. Philadelphia: Blakiston Company, 1943.

The author defines pharmacognosy as the science which treats of the history, production, commerce, collection, selection, identification, valuation, preservation and use of drugs and other economic materials of plant and animal origin. The aim of the work is to supply a systematic textbook for students of pharmacognosy, either from the morphologic or from the taxonomic point of view. Pharmacognosy is so wide in scope that few students can master it because of its generality as well as its specificity. The study of pharmacognosy is now confined almost entirely to schools of pharmacy, and even here the time given to it is becoming restricted more and more. Medical students are but little exposed to it. Textbooks of pharmacology have found it expedient to restrict pharmacognosy to the mere essentials of such drugs as digitalis, ergot and quinine, and many students cannot recognize any of these. Ever since Dioscorides compiled the Greek Herbal, the study of plant pharmacognosy has gradually decreased, especially during the last century. There is adequate reason for this decline. Medical students simply do not have the time to spend on it. The action of active ingredients and the thousands of organic preparations are more important in medicine than the study of pharmacognosy. Medical educators must confine their teaching to fundamental principles and their action. To them the action of the opium alkaloids is of much more importance than the structure of the poppy capsule. This book, however, is worth the attention of medical students and practitioners, at least as a reference work. For the student of pharmacognosy it is excellent, as indicated by the publication of the fifth edition. The book presents (1) morphologic considerations of drugs, (2) taxonomic consideration of drugs, (a) drugs of vegetable origin, (b) drugs of animal origin, (c) microanalytic methods. It is well arranged. The printing and illustrations are excellent, the text is clear and the statements are definite. For the student of pharmacognosy it can be recommended, for the library of the more general reader it is a worthy addition.

A Venture in Public Health Integration: The 1941 Health Education Conference of the New York Academy of Medicine. Cloth, Price \$1. Pp. 56. New York: Columbia University Press, 1941.

This book contains the proceedings of the 1941 Health Education Conference of the New York Academy of Medicine. Contributors to the symposium were Edward J. Stueglitz, M.D., Washington, D.C., who spoke on "The Role of Health Education in the Promotion of Optimal Health and in the Retardation of Degenerative Diseases," Edward L. Bernays, New York, on "Barriers to Health Education," and Allen Freeman, M.D., Baltimore, on "Health Education by the Private Practitioner, the Voluntary Agency and the Department of Health." To the experienced person in health education this material brings nothing new, but these three addresses taken together will give an excellent brief survey and introduction to the field of health education for the novice. The only serious criticism of the views expressed by these authors is their adherence to the prevalent lament, namely that the doctor is not sufficiently interested in health education and that medical ethics must be reinterpreted to give the doctor greater freedom as a health educator. The fact is, of course, that the Judicial Council of the American Medical Association and the House of Delegates have long recognized health education and have enabled and encouraged the physician to participate in it without violation of any principle of medical ethics. Another point often overlooked when the doctor is admonished for his lack

of participation in health education is that the primary responsibility of doctors is the care of the sick, but that in discharging this, their fundamental, obligation doctors perform day in and day out an incalculable amount of health education which can never be measured and charted because it is so intimately interwoven with diagnosis, therapeutics and the intangible doctor-patient relationships which enable the physician unobtrusively to guide his patient toward the way in which he should walk. If this is not health education, what is it?

A Manual of Experimental Embryology By Viktor Hamburger Cloth Price \$2.50 Pp 213, with 45 illustrations Chicago University of Chicago Press, 1942

Professor Hamburger's book is intended to be used as a laboratory guide in graduate or undergraduate courses in experimental embryology. It fulfils this function admirably by bringing together much information about operative procedures and the preparation of materials and of instruments which was previously not available in any single book. Clear step by step descriptions of all phases of operations on amphibian and chick embryos and on planarians (flat worms) are presented in such detail as to enable one not previously trained in this type of work to carry out successful experiments. There is a particular emphasis on simplicity of procedure and use of instruments which may be prepared in any laboratory. Thus, directions are given for the preparation of hair loops, glass needles, micropipets, microscalpels and microburners—instruments which suffice for the repetition of many classic operations. The more elaborate tools (iris knives, iridectomy scissors, watchmakers' forceps) are described and the places where they can be purchased are listed. There are excellent descriptive chapters on gastrulation in the amphibia and primitive streak formation in the chick, followed in each instance by a series of carefully thought out experiments. The illustrations are clear and numerous and serve to show instruments, operations and embryonic stages. Embryologists will find the normal series of stages of frog and salamander embryos particularly useful. Each chapter is followed by a short and well chosen bibliography. Methods of obtaining and caring for embryos of amphibian and chick are not overlooked. In summary, this book should serve as an excellent handbook for the use of those already working in this general field or of those who wish to begin transplantation experiments on the nonmammalian vertebrates.

The Hand Its Disabilities and Diseases By Condict W. Cutler Jr. M.D., F.A.C.S. Associate Surgeon Roosevelt Hospital New York. Cloth Price \$7.50 Pp 572 with 274 illustrations Philadelphia & London W. B. Saunders Company, 1942

The author has placed considerable emphasis on the anatomy of the hand and its relationship to methods of sound treatment. In addition to an excellent chapter on anatomy, the subject is brought up throughout the entire book and is enhanced by photographs of anatomic specimens and clearcut line drawings. The dangers of delaying adequate treatment of apparently minor infections until evidences of toxemia arise and the complications which may arise from the use of local and nerve block anesthesia in treatment of infections are emphasized. In the treatment of specific infections mention is not made of the use of tetanus toxoid, which is of special interest because of its use in the armed forces. Neither is anything said about the experimental drugs which may be the answer in the treatment of mycotic infections. The author's treatment of burns may find disfavor with some who do not care for the use of tannic acid, but his results appear to be good. Attention is called to the avoidance of delay in skin grafting of burns until an avascular scarred base is laid down. Fractures, compound and simple and dislocations, are concisely treated. In the majority of cases the most commonly accepted method of treatment is described and no attempt is made to introduce controversial material. The chapter on repair and reconstruction describes excellently the principles of skin grafting and nerve and tendon repair and could be read with profit by any one who may be called on to do such surgery on other parts of the body as well as on the hand. Congenital and acquired deformities, tumors and manifestations in the hand of constitutional diseases form the closing chapters. The relationship of the hand to the body as a whole is clearly defined and the necessity for systemic, as well as local,

treatment is emphasized. The works of others have been freely drawn on and due credit is given throughout as well as in references at the end of each chapter. Coupled with the material from the author's own vast experience, the book becomes one which should take a well deserved place on any physician's shelf.

Diseases of the Gastro Intestinal Tract By Asher Winkelstein M.D. B.S. Associate in Medicine and Physician in Charge of the Gastro Intestinal Clinic The Mount Sinai Hospital New York. Cloth Price \$2 Pp 195 New York Toronto & London Oxford University Press 1942

Public Health and Preventive Medicine By Morton C. Kahn M.A. Ph.D. D.Sc. Associate Professor of Public Health and Preventive Medicine, Cornell University Medical College New York. Volumes I and II. Cloth Price \$4 per set Pp 267 269 534 New York Toronto & London Oxford University Press 1942

Urology By William H. Mencher A.B. M.D. F.A.C.S. Associate Urologist Harlem Hospital New York. Cloth Price \$2 Pp 201 New York, Toronto & London Oxford University Press 1942

Gynecologic Surgery By Morris A. Goldberger M.D. F.A.C.S. Associate in Gynecology Columbia University New York. Cloth Price \$2 Pp 164 New York Toronto & London Oxford University Press 1942

These books are written in outline form and are officially designed for busy practitioners and medical students. They may be useful for the general practitioner who must look up quickly just enough information on which to "get by" on the treatment of some clearcut and relatively uncomplicated case. They may also be useful for the medical student studying for examination or for the physician whose formal medical training lies far in the background or who has specialized and who must review quickly fields other than his own in order to pass some state licensing examination.

Atlas of Ophthalmic Pathology Prepared at the Army Medical Museum Office of the Surgeon General U. S. Army from Material in the Registry of Ophthalmic Pathology By Elbert DeCoursey Maj. Medical Corps U. S. Army and others. Third edition. Paper Price \$5 Pp 142 with illustrations Omaha American Academy of Ophthalmology and Otolaryngology 1942

This is the third edition of the Atlas of Ophthalmic Pathology prepared at the Army Medical Museum from the material in the Registry of Ophthalmic Pathology by Col. J. E. Ash and Major Elbert DeCoursey. A new method of production enables this excellent atlas to be sold at a substantial reduction in cost and in larger quantities, so that the academy has now adopted it as a textbook for its home study course. There has been essentially no change in this new edition of the atlas from the previous edition, and it continues to be an excellent textbook for instructional purposes for both student and clinician.

Germany's Master Plan The Story of Industrial Offense By Joseph Borkin and Charles A. Welsh With an Introduction by Thurman Arnold. Cloth Price \$2.75 Pp 339 New York Duell Sloan and Pearce 1943

Long before the beginning of World War II, German industry had been endeavoring to set up a system for worldwide control over electrical equipment, drugs, chemicals and basic war materials. Many of the facts regarding this system of control are here made available by writers who have been in intimate touch with the investigations on the subject. Joseph Borkin was for many years economic adviser to the Antitrust Division of the Department of Justice. Some of the facts regarding the relationship of the German drug industry to some portions of the American drug industry will come as revelations to American readers and indicate the need for control over international agreements of this type in the future.

The Psychology of Supervising the Working Woman By Dr. Donald A. Laird Industrial Consultant with the assistance of Eleanor C. Laird Research Librarian. Cloth Price \$2 Pp 202 with illustrations New York & London McGraw Hill Book Company Inc. 1942

The opening chapters are a consideration of the history of the employment of women in industry and the factors and motivating forces which have brought about an increase. The remainder of the book is a tedious discussion of the physiologic, physical, mental and emotional differences of men and women as they affect their working capacity. Whereas the title indicates that the book might be of value to the employer or supervisor of women, it actually falls far short of giving practical suggestions or methods outside of making women comfortable at work.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT HOWEVER REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS BUT THESE WILL BE OMITTED ON REQUEST.

SMALLPOX VACCINATION—DURATION OF PROTECTION

To the Editor—During this wave of enthusiasm in the Philadelphia area I have had occasion to vaccinate one large group against smallpox. The puncture method was used. This group consisted of 389 factory workers. The inspection of results of the procedure showed positive takes in 326 of the 389 and 63 negatives. This represents approximately 84 per cent of individuals who were probably not immune to smallpox. Since this interpretation of the result is generally accepted I am curious to know whether or not in the opinion of experts this is the case. Could it be that a more potent vaccine is being used at the present time than has been used heretofore? Are we to consider these positive takes with the typical vesicle and local inflammatory reaction appearing from four to seven days after the procedure as actually cowpox? In this group I patient gave a history and showed the results by pockmarked skin at having had smallpox approximately thirty years ago. She too gave a positive reaction. If we are to interpret these as positive takes it probably indicates that this large group of persons was susceptible to smallpox. In the case of an epidemic the seriousness of the situation should not be taken lightly since this is a cross section of our working population.

Abraham Cohen, M.D., Philadelphia

ANSWER—The duration of the vaccinal protection and the manner of its disappearance are certainly a most important part of the practical side of vaccination. This question must be considered for the purpose of determining when precautions should be taken to renew the protection which has become deficient. The answer is unfortunately a complicated one, since there is evidence to show that the duration of absolute immunity after a single vaccination extends no definite period of time, but that it is subject to great individual variations. After a single successful vaccination in childhood it has sometimes been observed that all subsequent attempts at vaccination failed and that the individual never acquired variola in spite of frequent exposure to the danger of infection. In these cases it is certainly justifiable to assume that the single vaccination has caused a permanent protection just as one attack of variola usually renders the individual immune to any subsequent invasion of the disease. What is the rule for variola, however, is unfortunately only the exception for a single vaccination. It much more frequently happens that the individual reveals a fresh susceptibility, at least to inoculated vaccinia, after a more or less lengthy period of time. Cases are sometimes encountered in which a revaccination is successful after the short space of two or three years, but such occurrences are even still more exceptional than the instances of a permanent protection. They are consequently no guides for either practical purposes or legislative action and this is especially true, since the corollary of a similarly early attack of variola after vaccinia is as yet wanting. The renewed susceptibility to inoculated vaccinia, nevertheless, always makes one fearful lest an infection with smallpox would have been possible in these cases if the variolous virus had found an opportunity to effect an entrance into the system. If a longer period of time has elapsed since the vaccination, a secure protection against variola is to be no longer counted upon the epidemics of smallpox in the nineteenth century sufficiently demonstrated that the number of cases in individuals vaccinated but once was far from infrequent. The individuals who were vaccinated in the first year of life were scarcely ever attacked until after the fifth year, and it was not until the tenth year was reached that the number of individuals attacked rapidly increased. It might be stated from these observations that the average duration of the protective effect of a single vaccination is about ten years, and that it certainly does not extend much beyond this period. The vaccination statistics confirm this view to a certain extent, since they show that after the tenth year about 60 per cent (and over) of all individuals vaccinated in early childhood show a renewed susceptibility to inoculated vaccinia which is more or less pronounced. (Nothnagel's Encyclopedia of Practical Medicine, American edition, Philadelphia, W. B. Saunders Company, 1908).

There is no reason to doubt that approximately 84 per cent of the persons revaccinated recently in a certain group of workers in Philadelphia showed a considerable amount of susceptibility to vaccinia and supposedly to smallpox also. This would be more likely to be true had these people previously been vaccinated only once and at an early time in life. The fact that a person who had had smallpox showed a positive

take" is not surprising, because it is well known that, while a recent successful vaccination protects against smallpox, an attack of smallpox does not always protect against inoculated vaccinia. The findings of Rivers, Ward and Baird (*J. Exper. Med.* 69: 857 [June] 1939) clearly show that the potency of a vaccine lymph used for revaccination makes a decided difference in the number of persons who show incomplete protection against smallpox. The physician doubtless used a potent virus.

RADON SEEDS VERSUS TONSILLECTOMY

To the Editor—Recently I have heard many discussions regarding the application of radon seeds as a substitute for tonsillectomy. What is the consensus on this treatment? Can you refer me to some articles on the subject?

M.D., Massachusetts

ANSWER—Most of the reports concerning the substitution of radon seed application for tonsillectomy appear in the literature of the early 1920's and little is to be found since then. However, the otolaryngologists and radiologists appear to have reached certain conclusions in which most of them concurred and which apparently have changed little since then, namely the use of radon in case of hypertrophy or other nonmalignant diseases of the tonsils.

The methods employed consist in the use of surface application or the insertion of removable or permanent seeds directly into the tissues. Variations in technique are naturally manifold although they are all similar in their essentials. The details can be obtained from many of the articles hereinafter referred to.

S. Withers of Denver (*Laryngoscope* 32: 163 [March] 1922) favored the use of radon applications but felt that the experience up to that date was insufficient for forming a definite opinion.

C. F. Robinson (*Ann. J. Radiol.* 9: 558 [Sept.] 1922) reported 75 cases (inoperable) which he treated with good results.

F. E. Simpson of Chicago (*Radium Therapy*, St. Louis, C. V. Mosby Company, 1922) stated that in selected cases radium (radon) treatment may be substituted for operative removal of hypertrophied tonsils.

B. R. Smirly (*THE JOURNAL* Sept. 8, 1923, p. 800) opposed the substitution although he had had no personal experience with radium or radon.

W. A. Wells of Washington, D. C. (*South. M. J.* 14: 907 [Nov.] 1921, *Laryngoscope* 33: 681 [Sept.] 1923) believed that we can produce atrophy which "we may liken to normal physiological atrophy and all physical evidences of disease are made to disappear."

F. H. Williams of Boston (*Ann. J. M. Sc.* 168: 18 [July] 1924) reported 101 cases and advised the use of radon in selected cases.

J. W. Babcock (*Ann. Otol., Rhin. & Laryng.* 34: 834 [Sept.] 1925) opposed its use, although he himself had employed only x-ray therapy rather than radon. He reviewed 49 authors and found 28 to approve of 10 (including the author) who believed it was of little value, because he claimed that radon does not remove the tonsil as a potential focus of infection.

J. Coleman Scull of New York (*Beth Israel Hosp. Bull.*, Nov. 2, 1924, *N. Y. J. Med. Stat. J.* 32: 198 [Feb. 15] 1932, *Laryngoscope* 42: 620 [Aug.] 1932) reported over 200 cases and favored the use of radon in inoperable cases. He had good results.

S. J. Crowe of Johns Hopkins, Baltimore (*Arch. Otolaryng.* 33: 618 [April] 1941), advised the use of surface radon applications for treating recurrence after having treated more than 100 cases.

The consensus seems to prefer the use of radon or radium to tonsillectomy in inoperable cases (whatever the cause) or in treating recurrent growths following initial tonsillectomy. In view of the potential danger of radon application anywhere in the body it would be advisable to consult with a radiologist skilled in radon therapy before employing this method of treatment. However, operative removal of the tonsils is still the method of choice in dealing with uncomplicated diseased tonsils.

ALLERGY IN BUTCHER SHOP REFRIGERATOR

To the Editor—A patient with chronic sinusitis and rhinitis, a butcher apparently made worse by going in and out of the refrigerator. He had a vacation of six weeks last winter and his condition cleared entirely. Do you know of any means by which I could protect this man's nose from the cold air while in the refrigerator?

S. A. Olson, M.D., Glendive, Mont.

ANSWER—The data given in this inquiry suggest one of two possibilities. First, the patient may be sensitive to inhalants present in a higher concentration in the refrigerator than in the butcher shop. Either animal excretions, meats (sensitive to

odors) or molds may be present in much higher concentration in the refrigerator than elsewhere in the patient's environment. If this diagnosis is tenable, the patient should have similar trouble all the year round on entering the refrigerator. Conditions, however (the type of meat or fowl stored), may be different in the winter than in the summer. If he is mold sensitive he should have symptoms in the summer, especially during humid or rainy weather. The possibilities suggested should be investigated by clinical exposure to the various antigens separately, i. e. the effect of entering a damp basement, the effect of inhalation of the various molds found in a butcher's refrigerator. Cutaneous tests with the different allergens may be used to aid in confirming the diagnosis. If the patient is clinically sensitive to an allergen or allergens that cannot be eliminated, gradual hyposensitization by injection may be tried.

Physical allergy (cold sensitivity) is the second possibility suggested by the history. If this explains the symptoms the patient should have similar trouble when he is exposed to comparable temperature changes as when entering the refrigerator, i. e. when going outdoors during a cold day with no more protection from the temperature change than when exposed to the refrigerator temperature. This should be tried for confirmation of the diagnosis. If the condition is classifiable as physical allergy, an attempt may be made to increase the patient's tolerance by gradually increasing exposure to cold (ice rubs over a wide surface of the body, increasing the time of exposure gradually, cold baths, gradually decreasing the temperature). In addition, daily injections of histamine diphosphate may be tried in increasing doses. It is advisable to start with a low dose (about 0.1 cc of 1:10,000 solution). This dilution may be given once or twice a day in increasing doses until 1 cc of 1:10,000 solution is tolerated. The 1:1,000 solution of histamine diphosphate is then used, starting with 0.1 cc and gradually increasing the dose to about 0.5 cc, if tolerated by the patient. When the dose of 0.2 to 0.3 cc of the 1:1,000 solution is reached, the injections may be spaced at three to four day intervals. If the patient responds favorably to this treatment, the maximum dose reached without untoward symptoms may be maintained at once every three days to once a week for as long a period as required.

SHORT WAVE DIATHERMY FOR ANGINA PECTORIS

To the Editor—Can you furnish me with any information concerning the use of short wave therapy in the treatment of angina pectoris?

E. B. Miller M.D. Manistee Mich.

ANSWER—Short wave diathermy has been employed extensively by various European workers for treatment of angina pectoris. Although these European workers have said that its value is generally recognized, it would seem difficult to evaluate the clinical results in this disease because of the variable course which it tends to follow.

The usual procedure has been to apply an electrode directly over the precordium and another somewhat larger electrode over the back, or to place a pancake coil directly over the precordium. It is argued that the direct heating of the cardiac musculature tends to improve the circulation in the coronary vessels and also to reduce the blood pressure, which effects would tend to be beneficial in the presence of angina pectoris. The procedure should be employed only cautiously under careful and expert observation by trained cardiologists.

Although more than twenty European writers have reported favorably concerning the value of applications of short wave diathermy to the cardiac area, none of them seem to have made any comparative studies concerning its clinical usefulness as compared with other forms of treatment.

It has been pointed out by William Bierman (The Medical Applications of the Short Wave Current, Baltimore: William Wood & Co., 1938) that in the treatment of angina pectoris by means of short wave diathermy one should record the blood pressure every two minutes. If the pressure tends to rise during the session, the application either is discontinued or is diminished in volume. Bierman cites the work of many European physicians in treating angina pectoris with short wave diathermy. He mentions that Seigen treated 770 patients suffering from angina pectoris, employing short wave in addition to other routine forms of therapy. He had the opportunity of reexamining many of these patients several months after treatment. The electrocardiograms taken at the end of the treatment showed surprising disappearance of all pathologic changes seen initially. Bierman points out that there appears to be unanimity of opinion among the workers in this field that caution should be exercised in the administration of short wave current for the treatment of angina pectoris. Bierman concludes: "It is

difficult to prove any special value to the use of short wave current in the treatment of angina pectoris because spontaneous remissions occur in this disease, and because rest and other measures are applied concurrently."

One may conclude then that to date there is no conclusive evidence that short wave diathermy is effective in the management of angina pectoris.

CONTINUOUS DRIP THERAPY OF GASTRODUODENAL ULCER

To the Editor—How long can a patient be medicated with a small stomach tube by way of the mouth or nose in an attempt to treat a stomach ulcer temporarily by means of the various new aluminum compounds and the milk bicarbonate treatment recently mentioned in The Journal? I was glad to see several articles recently on the management of gastroduodenal ulcer but it is not yet clear to me just how many days or weeks a tube might be allowed to remain. I have a patient who is extremely nonsensitive locally to the presence of the tube in either the nose or the mouth with remarkable emotional equanimity. He is so emaciated that he dreads an operation at the moment and wants to try the alkaline treatments before submitting to an operation which an excellent physician told him was out of the question—absolutely the wrong thing in his case. I realize that no definite limits can be established for things of that kind and I recall that many of us felt years ago that intravenous solutions, transfusions and the like ought to be given someday and could be given someday over hours and perhaps days by the bold surgeon who threw aside some of the popular notions of blood clotting and the like prevalent in those days. This man has had a nasal tube leading to the cardia inserted for over two weeks but for several hours (up to eight) in each twenty-four hours after the first few days the tube has been removed to avoid nasal and esophageal infection and ulceration; the patient meanwhile being allowed to amble about the hospital, sipping on occasion the same milk bicarbonate solution which was being used in the drip along with other milk and egg drinks and aluminum jells which could not easily pass through the tube. Information is desired as to the prevalent opinion in matters like this even though I believe I shall have to resort to surgical treatment because of the deep penetration of the lesser curvature ulcer. What is the longest record of nasal stomach or stomatogastric intubation with no withdrawals or with temporary ones as I am carrying out?

John P. Rankin, M.D. Elyria, Ohio

ANSWER—According to Palmer (chapter on peptic ulcer in Diseases of Digestive System, edited by S. A. Portis Philadelphia, Lea & Febiger, 1941) "the administration of food or antacid or both by means of a continuous drip into the stomach has much to recommend it in the treatment of gastroduodenal ulcer. The feeding is in effect a fistula feeding eliminating the potent cephalic phase of gastric secretion. More complete control of the acidity of the gastric content can be maintained by the day and night use of the drip method than by any other procedure." The continuous drip method is not usually maintained for more than seven to fourteen days, occasionally for three to five weeks.

Winkelsstein, Cornell and Hollander (THE JOURNAL, Nov. 7, 1942, p. 743) have found that the majority of patients so treated experience little or no difficulty in retaining the intragastric tube especially when the soft latex tube is used. According to these authors, patients learn to administer the drip treatment to themselves and may continue this therapy at night for a period of many months and even for as long as two or three years. A possible disadvantage of the drip treatment is the associated dryness of the throat, which may lead to esophagitis or esophageal ulceration. This form of therapy is contraindicated in the presence of infections of the upper respiratory tract in order to avoid the development of pneumonic complications.

The ulcer of the lesser curvature described should heal completely or almost completely within three to four weeks of such therapy if it is benign. If healing is not proved roentgenologically or gastroscopically or both, a gastric resection is indicated because the ulcer may well be malignant.

WALKING ON TOES INSTEAD OF SOLES OF FEET

To the Editor—Will you please give me the significance or causes of a person's landing on his toes when walking instead of landing on the heel first as is usually done? Is this condition hereditary or is it acquired? I know of two persons who had this peculiar gait with no evidence of any present or past history of diseases or injury.

William Campbell, M.D., Valley City N.D.

ANSWER—In walking, sometimes normal persons will land on their toes instead of the sole of their feet. In Friedrich's disease (spinal heredoataxia) the foot becomes decidedly arched, shortened and stubby (pes cavus) and in walking the feet land on the toes. The condition is usually hereditary although it can occur in any disease in which there develops an excessive pull of the muscles attached to the foot. This is especially true in the pull of the muscles of the calf and sole. Thus infections in the foot and calf, injuries of the foot and leg, long continued posture as from a cast and spinal cord disease may result in such a type of walking.

DESICCATED THYROID IN HEART DISEASE

To the Editor—Dr Arnold Lorand of Carlsbad, Czechoslovakia in his book *Old Age Deferred* states that thyroid can be given in certain forms of heart disease. He says it is practically as useful as digitalis and can be given simultaneously with it. The directions accompanying the product *Proloid* states that this substance should be given only under the supervision of the physician and its use is generally contraindicated in heart disease and in hyperthyroidism. I realize of course that it is contraindicated in hyperthyroidism but I would be pleased to know why thyroid is contraindicated in heart disease.

M D, Tennessee

ANSWER—The only indication for desiccated thyroid in heart disease is the presence of hypothyroidism or myxedema heart. In patients with myxedema heart the size of the heart is increased and its action weak. Edema, commonly generalized, is present. Improvement does not occur following the use of digitalis but promptly sets in when thyroid is administered. This condition is not common. When myxedema heart does not complicate hypothyroidism, some improvement in the heart's action may also follow its use. However, patients with heart disease should be given desiccated thyroid with great caution because it may precipitate the onset of coronary thrombosis.

IDENTIFICATION OF FUNGI AND MOLDS

To the Editor—By means of which textbooks or by what authorities can the identification of a microscopic fungus be made? The organisms being homogeneous are present in large numbers on Sabouraud's medium contained in a Petri dish. They were obtained by exposure of the culture medium to the atmosphere of an anthracite coal mine. How can a photomicrograph of such a culture be made? Would the latter step be advantageous in the procedure of identifying the organism?

M D, Pennsylvania

ANSWER—A key to most of the genera of fungi is given in Clements and Shear's *The Genera of Fungi*, New York, H. W. Wilson Company, 1931. It refers to Latin descriptions in Saccardo, and these, or monographs dealing with the various genera, must be consulted in order to verify the identification. Short cuts are generally unsatisfactory either because they are misleading or because they omit most of the enormous number of genera of saprophytic fungi.

In identifying molds, the fungus must be isolated in pure culture and examined as soon as the characteristic spores are formed. The optimal time for examination varies widely. With two needles a bit of the mold from a suitable culture should be momentarily moistened in alcohol and then teased apart in a drop of 10 per cent sodium hydroxide or other mounting fluid on a glass slide. A cover slip is placed over the drop, and the specimen is ready for microscopic examination. The significant features are the size, shape, color and septation of the spores and the manner in which they are borne. A photomicrograph can be made in the usual way from this specimen but is helpful only as a record.

HOME PASTEURIZATION OF MILK

To the Editor—Could you tell me the name of a simple home apparatus for the pasteurizing of milk? A small apparatus such as could be used for an ordinary household is what I have in mind.

Roy G. S. Dougall, M.D., Cobleskill, N. Y.

ANSWER—It does not appear that any special type of apparatus is necessary for home pasteurization of milk. The United States Public Health Service recommends that the milk merely be heated over a hot flame to 155 F, stirring constantly, then the vessel should be placed immediately in cold water and stirring continued until the milk is cool.

ZOO ANIMALS AND PARASITIC INFECTIONS

To the Editor—Here as elsewhere the children delight in feeding the tame zoo animals by hand. The children's fingers come in touch at least with the animal's tongue and are thoroughly moistened by its saliva. I wonder if parasitic intestinal diseases cannot be transmitted that way particularly if the children eat as they doubtless often do without thorough cleansing of their hands possibly even out of the same popcorn box from which they have just been feeding the animals. The animals chiefly concerned are all more or less closely related to the deer family.

M D, Massachusetts

ANSWER—[This inquiry was referred to Dr Herbert L. Ratcliffe, pathologist at the Penrose Research Laboratory, Philadelphia Zoological Garden, whose reply follows.]

Since 1936 we have had here a so-called Baby Pet Zoo, where children may feed and fondle small animals of all types.

During these years the average annual attendance has exceeded 50,000 and we have not had any indication that children may become infected with intestinal parasites from these animals. There is, of course, a minor danger in that cysts of intestinal protozoa might be transmitted from apes and monkeys to children, but the only protozoan of significance would be *Endameba histolytica*, and our animals have been examined for this organism.

There is a decidedly greater danger that our anthropoids may become infected from the children rather than the reverse. As far as deer and related animals are concerned, these rarely carry parasites that might be infectious to man by simple contact.

OBESITY OR FRÖHLICH SYNDROME IN INFANT—
HORMONAL THERAPY

To the Editor—A woman has brought to me her boy, aged 2, who even at this early age appears to be an example of the Fröhlich syndrome. May I ask you to give me an opinion on the following questions: Is it too early to begin treatment? Is there any gonadotropic substance which can be given orally? For treatment either oral or by needle is testosterone propionate recommended?

M D, Michigan

ANSWER—The diagnosis of the Fröhlich syndrome depends on demonstration of obesity plus a genital dystrophy, usually this refers to hypoplasia of the genital organs. Unless this is demonstrably present in a 2 year old boy, the only safe clinical assumption is that one is dealing with obesity. It is never too early to begin appropriate dietary restrictions for the control of obesity.

There is no gonadotropic preparation which is active when administered orally. Testosterone propionate is not gonadotropic. It is substitution of a material believed to be the hormone produced by the interstitial cells of the testicle. Certainly it does not stimulate the testis, which is a requisite for a gonadotropic hormone. Testosterone propionate would not be used, therefore, in the treatment of a genital dystrophy unless it had been demonstrated that stimulation of the testis was impossible and substitution for testis activity is desirable. Such a situation is not believed to exist prior to the age of puberty.

MUCOSA OF BRONCHI AND SINUSES IN ASTHMA

To the Editor—Will you please furnish me with information on the changes that take place in the bronchial epithelium in asthma? Do the same changes take place in the epithelium of the mucous membranous lining of the nose and paranasal sinuses?

H. D. Coles, M.D., Chicago

ANSWER—The characteristic changes found in the mucosa of the bronchial tubes and sinus mucosa of asthmatic patients are the static edema of the submucosa appearing almost like a hyalinization and the presence of numerous eosinophils. The changes in the epithelium itself will vary according to the degree and duration of secondary infection. Therefore one may see much more advanced destruction of the epithelium of the sinus mucosa than is present in the bronchial tubes. At any rate these changes are not characteristic, consisting of the increase in the number of goblet cells, destruction of ciliated epithelium and replacement with cuboidal or squamous cells. Hyperplasia is nearly always present, and in the sinuses one frequently finds cystic degeneration and polyp formation.

LOCAL OR GENERAL ANESTHESIA FOR ADULT
TONSILLECTOMIES

To the Editor—To help settle an argument as to the relative merits of local or general anesthesia in tonsillectomies of adults only would you please answer the following: Given an adult with no complicating factors who presents himself for tonsillectomy, what is the trend today as to anesthesia? Is local or general anesthesia preferred?

Samuel Pritzker, Captain, M.C., A.U.S.

ANSWER—Local and general anesthesia with variations and refinements are both in use in the hands of capable surgeons for the removal of tonsils of adult patients. Each type of anesthetic has its merits and shortcomings. Furthermore local custom decrees to some extent which one is favored. It can be fairly said that there is no decided trend in a specific direction favoring one or the other. In New England the tendency remains to use general anesthesia. In other parts of the country, and particularly in the Middle West, local anesthesia appears to be the one most often chosen. All this applies only to normal situations as posed in the question.

THE CHOICE OF ANESTHESIA FOR SERIOUSLY WOUNDED PATIENTS

HENRY K BEECHER MD
BOSTON

The relationship of anesthesia to shock is a particularly close one in military surgery not only because of the frequency of the appearance of shock in warfare but also because anesthesia can be and often is the precipitating factor in the development of shock. Anesthesia can knock down the body's defenses and transform a compensated circulatory system into an inadequate one with the result that profound shock appears in an individual previously not in shock. Several mechanisms which function in this way are fairly well understood and although interesting, can scarcely be discussed here in detail, for my aim in this report is to set forth as clearly and as briefly as possible the considerations which determine acceptability or unsuitability of the common anesthetic agents for use in those who are seriously wounded. Emphasis is given to agents and technics which are suitable for use under circumstances of mobile warfare.

The material discussed here is limited to a consideration of the characteristics of real clinical importance as far as the several agents are concerned. The present report is not intended to be a review of the extensive literature on this subject. It is, on the contrary, a report based in large part on observations made in this clinic and laboratory. That the views expressed here reflect observations of others as well as our own goes without saying, since a considerable effort has been made to digest the many reports pertinent to the subject of anesthesia and shock.

Quite plainly definitive answers to all the questions that are asked on this subject cannot now be given, for information that is adequate to do so has not yet been obtained in many cases.

Unfortunately, many of the reports of the last war on this subject as well as reports coming out of this war have all too clearly been based on data obtained by men who were overwhelmed by routine duties so that careful observations could not be made. As a consequence of this it is not surprising that the net effect is one of confusion filled with contradictions. Final answers can come only from trained observers in the field. A few men reasonably free from routine duties could really settle some of these problems. Until they are more certainly settled than is now the case it would be folly to neglect experience gained in dealing with severely wounded patients in civil life.

Typical questions which urgently need complete answers from active military fronts are the following:

1 Is any agent better than ether for general surgery under field conditions? What are the limitations of ether? Where is it to be avoided if at all? By the use of a simple device¹ ether can be administered as simply as by "open drop" or cone methods and yet use only one-tenth the quantity of ether required by those methods. Does this have military value?

2 Does spinal anesthesia merit consideration for the seriously wounded, for the person in shock or in impending shock? (The majority of available reports are strongly against spinal anesthesia, yet it continues to be widely employed for the seriously wounded.) A carefully observed series based on objective data is an urgent need.

3 How much of the anesthesia load can the intravenous barbiturates carry in military surgery? What is their particular field of usefulness? What are their peculiar clinical limitations? Can they advantageously and safely supplement local anesthesia? Should the intravenous barbiturates supplant chloroform when a noninflammable general anesthetic must be used?

4 In the rare instances when cyclopropane will be available under military circumstances, does it have value adequate to justify great effort to make it available in base hospitals? How about its use for shocked individuals?

5 Can the anesthetic agents be used as therapeutic tools to delay or prevent shock?

At least partial answers to these questions emerge from the following consideration of the characteristics of the common anesthetic agents. No attempt is made to present here a well rounded pharmacologic or clinical discussion of these agents. The entire attention is focused on the qualities (of whatever nature) of these agents which suggest acceptance or rejection in the choice of the best agents for use under military circumstances.

ETHER

(a) *Desirable Qualities*—The great potency of ether permits an adequate oxygen supply, even if only room air is available. Good muscular relaxation is provided. A great factor of safety is present under this agent if gross overdosage occurs, respiration fails (intake stops) while the circulation remains unimpaired. The great factor of safety is of importance when anesthesia is administered by the unskilled, as often must be the case under military circumstances. (Ether excels all other safe inhalation agents with regard to the aforementioned points.) The excellent tolerance of even the impaired circulatory system for prolonged ether anesthesia is well established in man. While the foundation for this statement is good as far as "organic" impairment is concerned and on the basis of much more limited experience appears to be true also of the circu-

From the Anesthesia Service at the Massachusetts General Hospital and the Anesthesia Laboratory of the Harvard Medical School at the Massachusetts General Hospital.

1 Beecher Henry K. An Easily Transportable Apparatus for Anesthesia With or Without Compressed Oxygen. *War Med* 2: 602-608 (July) 1942.

latory impairment encountered in shock more data for man are urgently needed on this point. Man in shock appears to tolerate ether far better than animals in shock.

(b) *Undesirable Qualities*—Under ether anesthesia there is some tendency toward acidemia. Considerable disturbance of carbohydrate metabolism occurs under this agent (the blood sugar level is elevated from 100 to 200 per cent). The agent is inflammable and explosive. Ether is "irritating" to the mucous membranes of the respiratory tract. No adequate demonstration has yet been made that this characteristic is of any importance in morbidity or mortality of postoperative pulmonary complications. On the contrary, there is much positive evidence that this so-called irritant quality is of no clinical importance.²

DIVINYL ETHER

While divinyl ether is easily transportable and swift in its action, it probably will have little value in military surgery because of the difficulty of using it satisfactorily without a closed rebreathing apparatus and also because of its tendency to cause laryngeal spasm, profuse salivation, muscular twitchings, even convulsions, and liver damage. These effects may be the result of breakdown products arising from its chemical instability. The agent has many of the other disadvantages of diethyl ether.

CHLOROFORM

(a) *Desirable Qualities*—Chloroform can be administered smoothly with little equipment. It is easily transportable. It will neither burn nor explode. Because of its great potency, only a low concentration is needed in the inspired air, thus adequate oxygen can be obtained from the atmosphere. Good muscular relaxation is produced by it.

(b) *Undesirable Qualities*—The effects of chloroform in producing death through ventricular fibrillation, central necrosis in the liver and destruction of the tubules of the kidney might be overlooked because of the urgency of other considerations in military surgery if it was not for the profoundly depressing effects of this agent on the circulation. The heart rate is slowed, the strength of contraction is weakened, the cardiac output falls, the blood pressure is depressed. Acidemia occurs.

It is true that the administration of high concentrations of oxygen in the inspired air will help to minimize the liver damage, as also will a diet high in protein and in carbohydrate. Unfortunately, these measures will not prevent the disastrous circulatory effects of this agent.

The only good reason for employing chloroform is its lack of inflammability, a matter of great importance on shipboard. It can be pointed out, however, that with the use of a new and exceedingly simple anesthesia apparatus³ it is possible to administer "closed" ether with such economy that only a little need be at hand, with a resulting lessening of the ether fire hazard. This apparatus presents all the real advantages of the large cumbersome apparatus and yet in such a simple way that an orderly can administer the anesthesia under the direction of a surgeon. Particularly on shipboard, where a compact apparatus of this

kind may easily be available, it would seem to be possible to eliminate chloroform in favor of ether. However, naval officers, to the present time at least, have decided that chloroform is indispensable.⁴ (See also the discussion in this connection of the intravenous barbiturates, and of local anesthesia, to follow.)

ETHYL CHLORIDE

Ethyl chloride is easily transportable and adequate for brief general anesthesia. It is occasionally useful for induction of more slowly acting anesthetic agents, like ether, but in general ethyl chloride has the same drawbacks as chloroform and in addition to them, is inflammable. Its usefulness in producing local anesthesia is fairly well limited to such trivial procedures as opening of boils, even so, the tissue damage produced by the freezing is considerable and does not justify its use when better methods are available.

NITROUS OXIDE ETHYLENE, CYCLOPROPANE

Nitrous oxide, ethylene and cyclopropane all require the use and transport of steel cylinders and the use of cumbersome apparatus and require compressed oxygen for their successful employment, since neither cumbersome apparatus nor tank oxygen will be available in most cases, these agents will doubtless have little or no usefulness at military fronts, except perhaps in a few base hospitals.

In the case of nitrous oxide and ethylene, few metabolic effects are produced provided adequate oxygen is maintained. It is generally impossible to provide adequate oxygen if a surgical level of anesthesia is required in the case of nitrous oxide, even if compressed oxygen is available, for such a high partial pressure of nitrous oxide must be used that there is little room for oxygen. The same is true of ethylene although to a lesser extent. Only poor muscular relaxation is produced with either of these agents.

Nitrous oxide is not inflammable or explosive. On the other hand, both ethylene and cyclopropane are exceedingly explosive.

Cyclopropane⁵ produces deleterious cardiac effects and death occurs apparently from ventricular fibrillation in a relatively high number of cases. Aside from that effect, however, the circulatory system of animals in shock or in approaching shock appears to tolerate cyclopropane better than any of the other inhalation anesthetic agents (Evans and Beecher⁶) with the possible exception of ethylene. Whether this is true of man in shock is unknown. Both cyclopropane and ethylene have the further good quality that induction and recovery can occur in a matter of a very few minutes. Accordingly when it is necessary to explore the abdomen rapidly of a patient in shock or approaching shock, as for example when it is necessary to investigate with-

² This is discussed by Beecher, Henry K. Some Controversial Matters of Anesthesia for Thoracic Surgery. *J. Thoracic Surg.* 10: 202-219 (Dec.) 1940. Beecher, Henry K. and Adams, Ralph. Ether Anesthesia in the Presence of Pulmonary Tuberculosis. *J. A. M. A.* 118: 1204-1209 (April 4) 1942.

³ Without wishing to attempt to oppose their views, I should like to point out, however (with the simple anesthesia machine just mentioned) how little ether need be carried on board at a time. Comdr. Frederick R. Hook, M. C. U. S. Navy, in the Transactions of the American Surgical Association 59: 135, 1941, says: "We may assume that the maximum number wounded on capital ships will be 15 per cent of the ships complement. On one vessel carrying 2,000 men, 300 wounded might be anticipated in a given major engagement. If one third of the 100 required full general anesthesia is with ether for a major operation, the total quantity of ether needed would only be about 100 ounces. Thus less than 10 pounds of ether would be adequate for a major encounter—no great problem as far as bulk or storage is concerned, and as far as inflammability is concerned even if the severely wounded casualties were 100 per cent larger than those estimated for a given encounter, the total quantity of ether required on board would seem to me to be negligible in comparison with the other inflammable and explosive materials aboard. The remarks are offered only for consideration and are not in any way intended to be placed in opposition to current practices. Certainly many naval factors are concerned in this choice of which I am not aware."

⁴ Beecher, Henry K. An Appraisal of Cyclopropane. *editorial Surg., Gynec. & Obst.* 75: 797-799, 1942.

⁵ Evans, Everett J. and Beecher, Henry K. Unpublished data.

out delay the question of internal hemorrhage or perforated viscus, these two agents if available should on the basis of present information, be ranked as first choice. In such a case any anesthesia is undesirable but if it must be used, the quicker its induction and the quicker the recovery from it, the better it will be for the patient.⁶

INTRAVENOUS BARBITURATES (EVIPAL, PENTOTHAL SODIUM)

The intravenous barbiturates have now been used widely enough to permit some comparison with other agents. When these agents are used for major as well as for minor surgery the death rate attributable to the agent varies from three to ten times higher (good to poor clinics) than it is for ether. In the Massachusetts General Hospital, where these agents are used almost entirely for short procedures (ten to twenty-five minutes) on able bodied young patients, the death rate appears to be low (8,000 cases with no deaths). So much for the ordinary cases. Early in this series we learned that bad risk patients tolerate these agents poorly unless very small quantities of the barbiturate are merely used as supplements to local or spinal anesthesia. Even then, in an adequate series of cases it was learned that the use of these agents to supplement spinal anesthesia was liable to produce a fall in blood pressure. Bad risk patients, particularly patients with circulatory impairment, tolerate full barbiturate anesthesia poorly. This statement can be made with emphasis on the basis of a large series of cases. Under circumstances in which it is imperative to have a non-inflammable agent, it is possible that the intravenous barbiturates would make a better choice than chloroform. This point requires further clinical study.

We have learned on the basis of laboratory studies of these specific agents that in addition to their cardiac depressant action there are two outstanding characteristics that make their use hazardous under conditions often encountered in patients.

First, there is a progressive loss, finally a complete loss, of sensitivity of the respiratory center to its normal chief stimulus, carbon dioxide. The blood content of carbon dioxide may rise to depressant levels under these agents. Second, with the normal respiratory drive either inadequate or lacking, the respiration is driven by anoxic stimulation of the peripheral chemoreceptors, carotid and aortic bodies chiefly. Anoxic stimulation of these bodies is as effective in deep anesthesia as in light.

These facts, simple as they are, point to strong reasons why these agents are tolerated poorly by patients in poor condition. The anesthetist relies almost entirely on the respiration to guide him as to depth of anesthesia. Under these barbiturates the respiration is a dependable guide only if the patient is breathing a high concentration of oxygen, for only then will the peripheral chemoreceptors remain inactive and the progressive depression of the respiratory center by the barbiturate

be evident. In other words low blood oxygen by stimulating respiration even during deep anesthesia masks the true depth of anesthesia. Presumably compressed oxygen will almost never be available in the field so it would seem that the use of intravenous barbiturates should be limited in military surgery to brief, minor procedures or possibly used as a supplement to local anesthesia. This conclusion is reached not only because of the difficulty of determining and controlling depth of anesthesia in the field but also because of the demonstrated poor tolerance of the bad risk patient for full anesthesia produced by these agents. Possibly intravenous barbiturates should supplant chloroform for major surgery when a noninflammable general anesthetic is required.

SPINAL ANESTHESIA

Several facts have emerged from observations of the effects of spinal anesthesia which are pertinent to the anesthesia and shock problem. The most important of these are the following:

- 1 Blood pressure has a tendency to fall under spinal anesthesia. This tendency is so great and so serious that spinal anesthesia was practically discarded as a clinical tool until it was demonstrated that this effect could in most cases be prevented by the use of vasoconstrictor agents.

- 2 Vasoconstrictor agents are inadequate in a high percentage of cases to maintain safe levels of blood pressure during spinal anesthesia of patients who have been subjected to trauma or to hemorrhage.

- 3 In spinal anesthesia the vasomotor fibers are the first to be paralyzed and the last to recover. The extent over which this occurs is greater than the area where the pain response is eliminated, for a lower concentration of anesthetic can interrupt vasomotor control than can interrupt pain sensation. In interrupting vasomotor control, spinal anesthesia breaks down an important defense against shock.

Notwithstanding these facts, it is rather often argued that spinal anesthesia is still a desirable agent to use for the seriously wounded patient. Gordon-Taylor⁸ spoke for the best of English military surgery when he said recently "Spinal anesthesia spells certain euthanasia for the shocked abdomen."

It is difficult to understand why there are in this country as many as there are who advocate the use of spinal anesthesia for surgery of the seriously wounded and otherwise poor risk patient. Even now, with data coming in from our own fields of action, spinal anesthesia is not showing up well. In such cases the proponents are liable to hold that in these specific cases the spinal anesthetic was not properly administered. The following data are pertinent to this question.

It has been possible to obtain an interesting comparison of good and bad spinal anesthetics and of the relationship of spinal to ether anesthesia, as far as blood pressure lowering effects are concerned in the clinical data of the Massachusetts General Hospital (patients with perforated peptic ulcer). Part of these data were obtained under conditions in which the anesthesia was poorly administered and part in which it was well administered. It is interesting to compare the data from these two groups. It is strikingly demonstrated that under both good and bad circumstances the same ratio of blood pressure lowering (spinal anesthesia compared with ether) holds in the two cases, as shown in the table.

6 Speed of induction and speed of recovery are probably generally grossly overrated when a distinction is made between the three or four minutes required for cyclopropane and the ten minutes for ether. Occasionally, as in the aforementioned case, speed assumes real importance.

7 Others have reported these effects for other barbiturates. To the best of my knowledge the only two agents used to any extent for intravenous anesthesia had not been studied previously in this connection. Beecher, Henry K. and Moyer, Carl A. Mechanisms of Respiratory Failure Under Barbiturate Anesthesia (Evipal, Pentothal). *J. Clin. Investigation* 20: 549-566 (Sept.) 1941. Moyer, Carl A. and Beecher, Henry K. Effects of Barbiturate Anesthesia (Evipal and Pentothal Sodium) on the Integration of Respiratory Control Mechanisms. A Study Directed Toward Improvement of Methods for the Preclinical Evaluation of Anesthetic Agents. *J. Clin. Investigation* 21: 429-445 (July) 1942.

8 Gordon-Taylor, Gordon. The Changing Aspect of the Abdominal Surgery of Modern Warfare. *Practitioner* 147: 448-62 (July) 1941.

Patients undergoing suture of perforated peptic ulcer constitute a group good for study in the present connection for the following reasons. These patients are in our experience liable to go into shock. The group is composed chiefly of men (97 per cent). They are on the average able bodied and not old (average age about 44 years). These patients are seen usually within one-half to four hours of their injury. The reparative operation is more standardized probably than any other major one to be encountered. The abdomen is opened, a small hole in the stomach or duodenum repaired and the abdomen closed, anesthesia and operation require in almost all cases one hour.

In the years preceding 1934, little attention was given to anesthesia at the Massachusetts General Hospital. The anesthesia of this period can accurately be labeled as poor. In the nine year period 1925-1933, inclusive the records of 56 patients with perforated peptic ulcer contained enough data to permit inclusion here. In the nine year period 1934-1942 (September) inclusive 111 patients received either or spinal anesthesia for repair of a perforated peptic ulcer. They are divided as shown in the table.

It is clear from these data that the number of serious falls of blood pressure is great under poor spinal anes-

Results of Anesthesia of 167 Perforated Peptic Ulcer Patients at the Massachusetts General Hospital

Patients	Anesthesia		Patients Showing a Fall of Blood Pressure to 70 Mm Hg or Below		Ratio of Serious Blood Pressure Falls
	Number	Per Cent	Number	Per Cent	
Group 1 Poor anesthesia 1925-1933	36	Spinal 64	11	30.5	2:1
	90	Ether 36	3	10.0	
Group 2 Good anesthesia 1934-1942	71	Spinal 64	8	11.2	2:1
	40	Ether 36	2	5.0	

thesia and by no means negligible under well conducted spinal anesthesia. Improvement of anesthesia (the surgical procedure has remained the same) cut to one-third the number of patients showing a serious fall in blood pressure both under spinal and under ether. The ratio of twice as many patients showing a fall of blood pressure to shock levels under spinal as under ether anesthesia is strikingly constant in both groups.

Much further data could be marshaled to support the thesis that spinal anesthesia is a poor choice for surgery for the patient either in shock or in impending shock.

LOCAL ANESTHESIA

It is proper that local anesthesia should always be considered when it is important to have a noninflammable agent or when surgery is contemplated on the traumatized or exsanguinated patient and employed if the surgeon considers that it will be adequate for his task. The experience of the English in this war, however, has repeatedly shown that local anesthesia is poorly tolerated by the severely injured but conscious patient. Apparently the moderate discomfort occasionally associated with local anesthesia and the psychological injury resulting from the knowledge that he is being operated on is adequate to produce enough bad reactions to cause many English surgeons to favor general anesthesia for treatment of the severely wounded person.

When local anesthesia is used, the following will minimize the not infrequently harmful circulatory effects

of too great or too rapid absorption of the local anesthetic agent.

- 1 The addition of epinephrine hydrochloride (1:200,000 optimum final dilution) to local anesthetic solutions will prolong fivefold the effect of a given dose of procaine hydrochloride. This use of a vasoconstrictor agent will obviously greatly reduce the total quantity of procaine needed. [Vasoconstrictor agents should not be employed in local anesthetic agents under the following circumstances: (a) When the local anesthetic agent is injected around the genitalia, fingers, toes, ears or nose. If used here, sloughs may result. (b) When the local anesthetic agent is to be supplemented by cyclopropane, chloroform, ethyl chloride or avertin with amylene hydrate anesthesia. Ventricular fibrillation may result. Vasoconstrictor agents in local anesthesia should be employed only with great care if at all for patients with organic circulatory impairment.]

- 2 It must be remembered that the toxicity from absorption of local anesthetic agents increases in geometric proportion with increase in dose. While for an able bodied person it is usually safe to employ 150 cc of 1 per cent procaine if administered over an hour's time it does not follow that 75 cc of 2 per cent can be used rather, only about 35 cc of 2 per cent can safely be used in this period.

The technical difficulties to be encountered in the employment of local anesthesia while actually not great, will in the hands of those lacking special training in this field be associated with a considerable incidence of failure or only partial success and are time consuming. These facts will probably minimize the use of local anesthesia under military conditions.

SUMMARY AND CONCLUSIONS

- 1 The most difficult anesthesia problems that arise are those concerned with seriously wounded patients. Whenever possible, anesthesia and operation are avoided for patients in shock or in impending shock, until the patient's condition has improved as much as it will without surgery.

- 2 Whenever anesthesia must be administered to severely wounded patients, local anesthesia is employed, if considered adequate for the task at hand. This will rarely be the case for major procedures. Experience has shown that local anesthesia is in general best restricted to rather phlegmatic or apathetic patients, for whenever even minor surgical procedures must be carried out on apprehensive and suffering, badly wounded patients, surgical intervention under local anesthesia may be tolerated less well than under general anesthesia. An appraisal of the patient must be made as to his probable tolerance for the possible inconvenience and occasional discomfort of local anesthesia. Local anesthesia is always to be considered when a noninflammatory nonexplosive agent is needed.

- 3 For major procedures inhalation anesthesia is generally preferable. Ether anesthesia is the best all around single anesthetic agent for use when major surgery must be carried out. When, in the surgeon's judgment, great speed of induction and speed of recovery are of outstanding importance cyclopropane or ethylene is used, if available. This will probably rarely be the case.

- 4 Spinal anesthesia is poorly tolerated by severely wounded patients. Its use for such persons is often a major error.

- 5 Intravenous barbiturates (pentothal sodium, evipal soluble) are chiefly useful for producing general anesthesia for short procedures (twenty to thirty minutes) on robust young persons. They are often useful as supplementary agents when local anesthesia

proves to be inadequate. Intravenous barbiturate anesthesia appears to be preferable to chloroform for major surgical procedures when the use of a noninflammable, nonexplosive agent is imperative.

6 In studying the relationship of anesthesia to shock I have come to the following conclusions concerning clinical material

(a) Even in large civil hospitals where many accident cases are received the number of patients in shock or in seriously impending shock who must be operated on at once are far too few to permit any adequate civil study of the effect of the common anesthetic agents in shock. In the great majority of cases in civil life, when serious wounds are present, anesthesia and operation are properly deferred until the condition of the patient is so improved that he no longer constitutes a real test of the anesthetic agent in shock.

(b) Valuable and at present nonexistent data concerning the role of anesthesia in shock can be obtained with simple observations of the trend of the pulse and the blood pressure during operation under various anesthetic agents and their relationship to the appearance of shock. Accordingly, anesthesia is one of the few subjects in the field of shock which can profitably be investigated without hampering or delaying in any way the patient's treatment. Valuable anesthesia data can be obtained so simply that the confusion often attending the treatment of large numbers of seriously wounded men need not be increased by such studies. Probably few data of any real value can be obtained unless trained observers free from routine duties are on hand to get them. The conflicting reports from the active fronts have already demonstrated in this war as they did in the last one that catch-as-catch-can data obtained by busy clinicians whose primary duties lie in other fields are worse than useless—they are misleading.

(c) The shock problems fall sharply into two groups: (1) the complex, difficult, interesting problems which will only with great luck be solved in time to be of benefit in this war and (2) the simple, often dull, but urgent problems to which solutions are needed, and unlike those in 1, almost certainly can be solved. The requirement is an abundance of clinical material, far more than can be obtained in civil life (see first paragraph of summary). The best choice of anesthesia for various types of seriously wounded military patients has not yet been demonstrated. It can be determined only by trained observers under military conditions.

(d) In the entire consideration of shock, one of the few fields where we can be certain of effecting real improvements in current practices in time to be of benefit in this war is in the field of anesthesia and its relationship to shock. Little can be accomplished, even in this, unless far more clinical material is made available to trained observers than is now the case.

A Great Surgeon—The mechanics of medicine and surgery can be acquired quickly by any reasonably intelligent person, but the morals of medicine and surgery can be acquired only slowly and require a painfully long period of training and preparation. If it can be said of any man that he is "an operating fool," the adjective "operating" is redundant. A great surgeon is not a man who has mastered the mechanics of a simple appendectomy or tonsillectomy or any other "ectomy," he is a man who knows not only how to operate but on whom an operation should be done and, more important, on whom an operation should not be done. Surgeons are great because they have sound judgment rather than mere mechanical skill.—Olson, *J G Time*, Oct 26, 1942, p 6

THE EFFECT OF EXTERNAL TEMPERATURE ON SHOCK

AN EXPERIMENTAL STUDY

K G WAKIM, M.D., PH.D.

AND

W D GATCH, M.D.

INDIANAPOLIS

Shock is a type of peripheral circulatory failure which causes a profound disturbance in the physiologic mechanisms of the body and leads to a syndrome exhibiting, among its manifestations, hemoconcentration, oligemia and a generalized peripheral vasoconstriction. In these unparalleled times, when injuries resulting in shock are not limited to our armed forces in combat zones all over the globe but may also occur *en masse* in our civilian population as a result of air raids or industrial accidents, a thorough investigation and careful appraisal of some of the methods employed in the treatment of shock are most timely. In the treatment of shock the application of heat is too much stressed. The public, as well as the physician, uses heat in abundance in the treatment of shock from whatever cause. In first aid instructions one is taught to apply hot water bottles, hot bricks or heated stones to the extremities and sides of an individual in shock.¹ That not only warmth but heat is recommended for the treatment of shock can be inferred from the warning expressed in books that great care must be taken to prevent the infliction of severe burns from the hot water bottles used on the person in shock.

In the light of our understanding of the physiologic principles involved in shock, this emphasis on the application of heat to shocked individuals made us interested in determining, experimentally, the influence of temperature on shock as well as the effect of heat on the survival time of shocked animals. From the evidence observed in our experiments, we learned that the application of heat or of cold greatly shortened the survival time of anesthetized animals in experimental shock, while the animals that were placed at room temperature and those placed on warm water bottles slightly above room temperature, after shock was produced, had a much longer survival time. An external temperature in the neighborhood of body temperature proved to be optimal. With the exception of a few of the animals that had to be killed after having survived beyond twenty-four hours, no attempt was made to apply any measure to prolong or to shorten the life of any of the animals used in this investigation.

In 1914 Mann² performed experiments involving exposure of abdominal viscera and demonstrated the significance of the loss of circulating fluid in shock. The effective circulating blood volume is decreased, and accompanying the decrease is a great reduction in volume flow. Blalock and Levy³ demonstrated a sharp decrease in blood flow in hemorrhage and in intestinal trauma. Anoxia predominates whenever diminution of

blood flow becomes severe. Aub and Cunningham⁴ observed in shocked cats and Freeman, Shaw and Snyder⁵ noted in shocked patients a decided decrease in the oxygen content of venous blood. The loss of plasma due to dilatation of the capillaries and increase in their permeability was attributed by Krogh⁶ and by Landis⁷ to anoxia. Blalock⁸ rightly emphasizes the fact that diminution in circulating blood volume is the initial and most important alteration in shock. Brooks and Duncan⁹ observed that the temperature of a part is of great importance in determining the survival period of ischemic tissue. Allen,¹⁰ in a study of surgical considerations of temperature in ligated extremities, noted that shock is more likely to accompany constriction of the circulation of the thigh if the local temperature is high than if it is low. Lahz¹¹ states that the optimum temperature for exsanguinated tissues is much lower than for normal tissues and that the former can be severely damaged by heating agents. Blalock and Mason¹² studied the effects of heat and of cold on large dogs in which shock had been produced either by removal of about one third of the blood volume or by trauma to

Fig 1—Diagrammatic representation of the constant temperature platform pump and thermostat

one of the posterior extremities. They concluded that significant elevations of temperature are more disastrous than depressions of similar degree.

METHODS

Dogs, rabbits, guinea pigs and rats were used in this study. Of each species, animals of practically the same weight (litter mates whenever possible) were selected and divided into six groups: a, b, c, d, e and f. Soluble pentobarbital was the only anesthetic used. The rat experiments in this communication were performed on black, hooded and albino litter mates unilaterally adrenalectomized four to five days previously. The rats and guinea pigs were anesthetized by subcutaneous

administration of 5 mg of soluble pentobarbital per hundred grams of body weight. The rabbits and dogs were anesthetized by intraperitoneal injection of 30 mg of soluble pentobarbital per kilogram of weight. In rats, shock was produced by either of the two commonly known methods, namely by traumatization of the posterior extremities or by exposure of the abdominal viscera and intestinal stripping. Since it was observed that trauma to the extremities did not produce a satisfactorily uniform shock in rats, exposure of the abdominal viscera and intestinal stripping was the only method used in producing experimental shock in the dogs, rabbits and guinea pigs included in this communication. After the production of shock each animal of group a was placed on an ice bag at 5 C (41 F), each animal of group b was placed on a bag at room temperature, 25 C (77 F), each animal of group c was placed on a warm water bottle at 35 C (95 F), each animal of group d was placed on a warm water bottle at 45 C (113 F), each animal of group e was placed on a hot water bottle at 50 C (122 F), and each animal of group f was placed on a hot water bottle at 55 C (131 F). The bags used were ordinary clinical rubber bags of the same size shape and material and were wrapped in one layer of cloth while in use. After shock was produced the survival time of each animal of the six groups and the average survival time of each group were determined and tabulated. To determine the degree of hemoconcentration the amount of hemoglobin was determined at intervals by means of the Sheard-Sanford photometer¹³ before and after shock was produced. All the large animals (rabbits and dogs) and some of the small ones were placed on a specially constructed constant temperature platform connected by means of an Eastern centrifugal pump (fig 1) to a thermostat set at the required temperature. The blood pressure of the large animals was recorded on a revolving kymograph by means of a mercury manometer connected to a glass cannula in the common carotid artery. A 3.5 per cent solution of sodium citrate was used to prevent coagulation in the arterial cannula.

RESULTS

Rats—The rats placed on hot water bottles at a temperature of 55 C after the production of shock, whether by intestinal stripping or by trauma to the extremities, died within a period of two hours. Their average survival time was 1.26 hours. The temperature of the water dropped from about 55 C to about 45 C in the first hour and to about 38 C by the end of the second hour. Most of the rats that were placed on an ice bag after shock was produced lived a little longer than those placed on the hot water bottle at 55 C. Their average survival time was 2.54 hours. The rats that were placed on a hot water bottle at 45 C after shock was produced had an average survival time of 3.36 hours. All the rats that were kept at room temperature or were placed on a warm water platform the temperature of which was maintained at 35 C survived much longer than either the group that was heated or the group that was chilled. The minimal survival time of the group that was kept at room temperature (25 C) was 14.83 hours. Several animals were killed after they had survived more than twenty-four hours. The average survival time of the rats that were exposed

The average hemoglobin value for the rats before the production of shock was 15.5 Gm per hundred cubic centimeters. The average hemoglobin value for the rats in shock from intestinal stripping was 21.2 Gm per hundred cubic centimeters, that of the animals in shock from trauma to the extremities averaged 16.9 Gm per hundred cubic centimeters. This difference in hemoglobin concentration of the rats in shock produced by intestinal stripping as compared with those in shock by trauma to the extremities is attributable to the loss of blood due to hemorrhage into the traumatized extremities.

Guinea Pigs—The guinea pigs that were shocked and placed on ice bags at 5 C had an average survival time of 0.93 hour, those placed at room temperature had an average survival time of 17.28 hours, those placed on warm water at 35 C had an average survival time of 18.14 hours, those placed on warm water at 45 C had an average survival time of 5.53 hours, those placed on hot water at 50 C had an average survival time of 3.18 hours, and those placed on hot water at 55 C had an average survival time of 1.70 hours. Table 2 gives detailed data on the individual guinea pigs used in each group.

Before shock, the guinea pigs had an average hemoglobin content of 16 Gm per hundred cubic centimeters of blood. Prior to death from experimental shock the

value for hemoglobin rose to an average of 20.2 Gm per hundred cubic centimeters.

Rabbits—The rabbits that were placed on ice bags at 5 C after shock was experimentally produced had an average survival time of 3.41 hours. Rabbits placed at room temperature after the production of shock had an average survival time of 7.62 hours, those which were shocked and placed on warm water at 35 C had an average survival time of 8.87 hours, those placed on water at 45 C after shock had an average survival time of 4.66 hours, those placed on water at 50 C after shock had an average survival time of 0.78 hour. One rabbit was shocked and kept on water at 55 C, it survived only 0.41 hour.

Before shock was produced the rabbits had an average hemoglobin content of 12.1 Gm per hundred cubic centimeters of blood. Prior to death in experimental shock the value for hemoglobin rose to an average of 16.6 Gm per hundred cubic centimeters.

The mean arterial pressure measured by a mercury manometer connected to the common carotid artery of the rabbits averaged 115 mm of mercury before shock and 65 mm of mercury immediately after the production of shock. Throughout the experiment the blood pressure gradually declined until it reached 0 at the time of death of the animal (fig. 2).

Dogs—The 2 dogs that were placed on an ice bag at 5 C after shock had been produced had an average survival time of 2.29 hours, 2 dogs that were placed at room temperature (25 C) had an average survival time of 14.25 hours, the 2 that were placed on warm water at 35 C had an average survival time of 16.58 hours, 2 dogs that were placed on warm water at 45 C had an average survival time of 10.91 hours, the 2 dogs

TABLE 2—*The Effect of External Temperature on Experimental Shock (Guinea Pigs)*

that were placed on hot water at 50 C had an average survival time of 3.87 hours, and the 2 that were placed on hot water at 55 C had an average survival time of 3.5 hours.

Before shock the dogs had an average hemoglobin content of 13.1 Gm per hundred cubic centimeters of blood. Prior to death in experimental shock the value for hemoglobin rose to an average of 20.1 Gm per hundred cubic centimeters.

The mean arterial pressure measured by a mercury manometer connected to the common carotid artery of the dogs averaged 150 mm of mercury before shock and 105 mm of mercury immediately after the production of shock. Throughout the experiment the blood pressure gradually declined until it reached 0 at the time of death of the animal.

The experiments on rats, guinea pigs, rabbits and dogs in shock yielded similar curves of survival time plotted against the various external temperatures employed in this study. Temperatures below that of ordinary room temperature and those above 45 C have deleterious effects on shocked animals. Figure 3 gives a composite picture of the influence on the survival time of the various external temperatures in contact with the body of animals in experimental shock.

In order to determine the effects of the various temperatures on normal anesthetized animals as compared with their litter mates under identical conditions, but in experimental shock, controls of the various species used were anesthetized and placed at the various temperatures that were used for the shocked animals. The controls for each group were kept at the specified temperature for a period equivalent to the average survival

individual. The reflex peripheral vasoconstriction is nature's protective mechanism to provide a decrease in vascular capacity as an adaptation to the decrease in blood volume, while the application of heat prevents the action of this reflex.

We have employed various gradations of external temperature in order to determine the ranges of temperature which are deleterious and those which are favorable aids in maintenance and survival of animals in shock. We found that external temperatures in the neighborhood of body temperature are favorable while anything below room temperature or much above body temperature is not only unfavorable but deleterious and hastens the fatal outcome. In fact Mann¹⁴ was able to produce shock in animals by the use of excessive heat (60 C) or cold (ice water). Excessive heat will do harm to the shocked organism in several ways.

1 It will produce a widespread superficial vasodilatation and distribution of blood to nonessential parts and thus counteract the protective natural reflexes that brought about peripheral vasoconstriction in the skin and neighboring tissues which are not so vitally in need of blood during the emergency of shock. This protective superficial vasoconstrictor reflex was brought about

Fig. 2—Chronologic changes in arterial blood pressure during experimental shock. The temperature in contact with the animal's body was 50 C.

time of the shocked animals of that group. All the control animals anesthetized and placed at room temperature, at 35 C and at 45 C recovered from anesthesia and remained normal thereafter. Of the controls placed at 50 C, the dogs, rabbits and guinea pigs survived and remained normal thereafter, but 50 per cent of the rats died and the other 50 per cent survived and remained normal thereafter. Of the control animals placed on ice bags at 5 C, only the rats died, while the guinea pigs, rabbits and dogs survived and were normal thereafter. These control data indicate that both extremes of temperature, the ice bag at 5 C and the hot water above 50 C, have deleterious effects even on normal animals.

COMMENT ON THE PHYSIOLOGIC MECHANISMS INVOLVED

Among the physiologic mechanisms which nature calls into play to compensate for the decrease in blood volume during shock is an immediate generalized peripheral vasoconstriction which brings about a reduction in the capacity of the vascular tree. This reflex vasoconstriction manifests itself in the blanching of the skin and contributes to the sensation of cold experienced by the individual in shock. The blanching of the skin and the cold sensation associated with it caused many to be overzealous in applying excess heat in cases of shock. This is done without realizing that heat would merely work against the efforts of nature by bringing about, among other things, a peripheral vasodilatation and thus defeat the purpose of saving the shocked

to serve the purpose of narrowing the capacity of the vascular tree to cope with the diminished blood volume (oligemia and hemoconcentration) in shock. Bazett¹⁴ states that simultaneous heating of the whole surface of the body would increase the blood content of the skin by about half a liter. Prinzmetal and Wilson¹⁵ reported an increase in the blood flow in the arm from 17 cc per hundred cubic centimeters a minute in a bath at 24 C (75.2 F) to a flow of 149 cc in a bath at 45 C (113 F). This is due mostly to an increase in the cutaneous circulation. On immersion of the foot and leg in water at a temperature of 40 to 47 C (104 to 116.6 F) Benson¹⁶ obtained an average increase of 276 per cent in the volume of the limb. In shock, in which the blood volume is significantly reduced and concentrated, heating the skin brings the blood to the heated body surface and thus reduces the blood flow to vital structures such as the central nervous system and myocardium. It thus becomes evident that heating the shocked patient defeats the purpose of trying to save him because a large part of his blood will go to the skin. However, we do not imply here that the patient should be left shivering on the roadside to die from cold, we mean he should not be overheated. We firmly believe in wrapping the patient up in blankets and

keeping him comfortable and warm but not hot. The evidence presented in this report indicates that it is better to err on less heat than on more heat in such circumstances.

2 Excessive heat will increase the metabolism and the oxygen requirement of tissues. Metabolic activities of tissues are chemical reactions, and it is a well known fact that, within certain limits, the greater the increase in temperature the faster the rate of the chemical reaction. In the presence of an already existing anoxemia in shock, overheating the patient necessitates the utilization of more oxygen and hence leads to a more severe anoxemia, which will increase capillary damage and capillary permeability and may terminate fatally. Landis¹⁷ has definitely shown that vasodilatation increases capillary pressure and consequently the latter results in increased transudation through the capillary wall. The loss of fluid from the vascular system and its accumulation in the tissues will increase the edema. The rate of this transudation and edema formation will be hastened in the presence of a high temperature, and consequently the oligemia and hemoconcentration become worse. The subnormal temperature recognized as a part of the shock syndrome may act as a protective mechanism because it decreases the rate of metabolic activity of the tissues and consequently reduces the demand of the body for oxygen which is not sufficiently available. Blalock and Duncan¹⁸ express the opinion that the favorable effects of the application of ice to injured extremities is due to a lowering of the metabolism of the part during the period of anoxia.

3 Excessive heat is likely to increase perspiration and consequently promote dehydration. The promotion of dehydration, in the presence of hemoconcentration and oligemia already existing in a state of shock, will create a vicious cycle the outcome of which will be a greater hemoconcentration, which is bound to lead to untoward effects.

4 The burns often produced when hot water bottles are applied to semicomatose patients are so familiar to the clinician that they need only be mentioned here.

The following are the physiologic mechanisms involved in the production of superficial vasodilatation as a result of application of heat to the skin.

1 The direct local dilator effect of heat on the blood vessels in the skin and neighboring tissue. This dilator reaction starts immediately and lasts as long as the heat stimulus remains in contact with the skin. Freeman¹⁹ demonstrated the direct dilator effects of heat on blood vessels in normal and in sympathectomized hands. Trotter and Davies²⁰ showed such direct vasodilator effects of heat on the blood vessels in completely denervated areas of skin. Lewis²¹ believes that heat increases the concentration of vasodilator substances in tissues and that this leads to vasodilatation in the heated areas.

2 Central hypothalamic inhibition of vasomotor tone induced by the rise of temperature of the circulating

blood. This takes place after the blood gets heated enough to stimulate the heat regulating center and persists until either the center fails or the heat is taken off and the temperature of the blood returns to normal. The central action is manifested by the delayed induction of vasodilatation in the vessels of the arm when the feet are placed in hot water for some time. This appears after the body temperature becomes elevated.²² The impulses for such central action are transmitted through nerve tracts and are abolished from completely sympathectomized extremities.

3 Reflex inhibition of vasomotor tone. This includes the well known axon reflexes of the vessels of the skin and other types of reflexes.

All these points support the fact that the wisest thing to do with persons in shock is to avoid exposing them to cold by wrapping them in blankets but too much heat is contraindicated and the wholesale use of hot water bottles around the body of the patient in shock should be condemned. The room of the shocked patient should be kept around 85 F, which is sufficient

Fig 3—The average survival times of different species of experimentally shocked animals which were placed at various external temperatures.

to give him a comfortably warm environment. We firmly believe in wrapping up a shock person with blankets and in keeping him comfortably warm, but we strongly advise against chilling or overheating him. As long as whatever is lost, whether it is plasma or whole blood, is not replaced, overheating will counteract rather than work favorably with nature's protective reflexes.

SUMMARY

The effects of various external temperatures in contact with control and experimentally shocked animals were investigated. Cold and heat proved to be deleterious to the life of animals in shock. An external temperature in the neighborhood of that of the mammalian body seems to be optimal for the survival of shocked animals. These findings justify the conclusion that as long as whatever is lost, whether it is plasma or whole blood, is not replaced, heating or chilling shocked animals is harmful, while keeping them comfortably warm contributes favorably toward their survival.

USE OF ULTRAVIOLET RADIATION IN REDUCTION OF RESPIRATORY CROSS INFECTIONS

IN A CHILDREN'S HOSPITAL FINAL REPORT

ELIZABETH CHANT ROBERTSON, M.D.

M. ELIZABETH DOYLE, M.A.

AND

FREDERICK F. TISDALL, M.D.

TORONTO

Following the installation in this hospital of a new operating room equipped with a battery of eight Westinghouse Sterilamps and an air changing system counts were made of the bacteria in the air of this room. Either of these agents reduced the number of air borne bacteria and the combination of the two was very effective.¹ This suggested the possibility of using similar means to reduce the number of cross infections in the infant ward.

In order to test the efficacy of various barriers to the spread of air borne bacteria, an experimental room was set up in the laboratory.² It consisted of a series of open door cubicles the entrances of which were 4 feet wide and 6 feet 2 inches high. Around the cubicle entrances, General Electric Ultraviolet Germicidal lamps (15 watt T8) were mounted with baffles in front and behind them so that a narrow curtain of ultraviolet radiation was thrown across the entrances. The number and arrangement of the lamps and the extent of the partitions at the sides of the cubicles were varied until a satisfactory combination was found. Their effectiveness was determined by spraying diluted cultures of *Bacillus prodigiosus* into the air and taking air samples with a Wells air centrifuge³ in various parts of the room. An air changing system was also installed and the best positions for the supply and exhaust vents were similarly determined.

Very few organisms passed from one cubicle to another with the following arrangements:

1 Six ultraviolet lamps mounted around the cubicle entrances

2 Partitions above the entrances extending to the ceiling

3 Side partitions from floor to ceiling

4 An air inlet near the floor at the back and an exhaust on the ceiling near the front of each cubicle

Shorter partitions and fewer lamps were less effective.⁴

RESULTS WITH ULTRAVIOLET RADIATION BARRIERS IN THE INFANT WARD

A room in the infant ward was then remodeled embodying the information obtained in this preliminary study. It provided accommodation for 6 infants under 6 months of age. The floor plan is shown in figure 1. Six ultraviolet lamps were mounted around the outer door which led into the vestibule used by the nurses,

6 more around the inner door which led into the room proper and 6 more around each of the cubicle entrance where there were no doors. The details of the position of the lamps and reflectors are shown in figure 2. The room was heavily insulated but since there was no cooling apparatus in the system there were great variations in the temperature and humidity. A small basin with foot controlled taps was installed near the front of each cubicle. A cubicle is shown in figure 3.

Before this ward was put into use, experiments were carried out to check the efficiency of the radiation barrier. The Wells test for sanitary ventilation was used, with *B. prodigiosus* as the test organism, as described in a previous paper.¹ The efficiency of the lamps was found satisfactory when no air changing was used or when the air was changed four, six or nine times an hour. Nine air changes an hour were therefore used.

When the apertures of the boxes in which the ultraviolet lamps were mounted were 3 inches wide, the bactericidal effect was excellent but the nurses suffered from burning of the skin. The apertures were therefore reduced to 1½ inches. They were still effective but no longer caused burning provided the inside walls of the

FIG. 1.—Plan of room equipped with ultraviolet lamps. Arrows show direction of ultraviolet rays.

boxes were painted a dull black. The reflectors behind the lamps were made of aluminum.

Dr. L. R. Koller of the Research Laboratory, General Electric Company, Schenectady, N. Y., determined the amount of ultraviolet radiation in various parts of the room. At the back of the cubicle where the baby's cot was placed there was so little that it could not be measured. All members of the staff wore tinted glasses when working in this room. No other precautions were necessary for their protection. The nurses were instructed not to hold any infant near the doorway of the cubicle, and no case of burning or conjunctivitis occurred.

Four ultraviolet lamps, two on each side, were mounted in the air duct, which was 14 inches by 14 inches in cross section. This duct carried outside air into the room. The air passed the lamps at a rate of 218 linear feet a minute. To test the bactericidal power of these lamps, diluted broth cultures of *B. prodigiosus* were sprayed directly into the duct 2 feet ahead of the first lamps. Samples of duct air before and after passing the lamps were then taken simultaneously with two Wells centrifuges. The results obtained in one test are shown in table 1.

Similar results were obtained in five other tests and it was concluded that the air entering the room through

the air conditioning system was practically sterile. Previous Wells samples of outdoor air, taken at the level of the air intake showed 2 to 3 organisms per cubic foot. No recirculated air was used in this room, but the ultraviolet lamps were mounted in the ducts in case there were some leaks in the system.

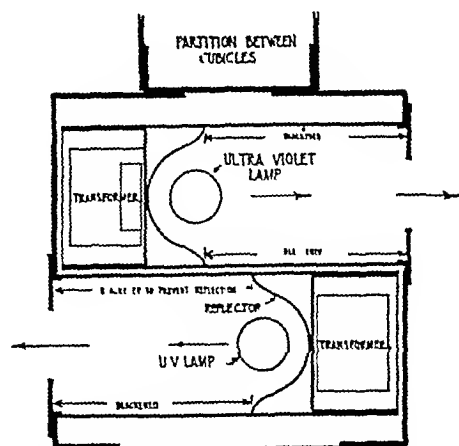

Fig 2—Mounting of ultraviolet lamps in posts between cubicles

To show whether this type of room was effective in practice we compared the incidence of respiratory cross infections among infants treated in it with that among similar infants in one of our usual unpartitioned rooms of the same size where the 6 cots were spaced around the walls. This room was ventilated by two windows and a transom over the door. This was called the first open control. The same physicians, nurses and maids worked in the two rooms. The nurses did not work elsewhere. After the babies in these two rooms were under observation for about five months, a second of the usual open rooms which accommodated 6 infants was used as another control. This was known as the second open control room. The babies in this room were nursed under the usual ward conditions which meant frequent changes of nurses.

The admissions were divided between the three rooms, and most of the babies were "clean," that is free from respiratory or other infections, when admitted. If a baby

TABLE 1—Bactericidal Effect of Lamps in Air Duct

	Number of Colonies per Cubic Foot of Air		
	Before Passing Duct Lamps	After Passing Duct Lamps	Percentage Killed
1st sample	14 330	12 460	Lamps off
2d sample*	13 060	351	Lamps on
3d sample	14 700	397	97
4th sample	12 550	368	97
5th sample	12 500	426	97

* The ultraviolet lamps were turned on immediately after the first sample was taken.

came in suffering from a respiratory disease which apparently cleared up, we did not consider the appearance of pyrexia, running ears, running nose, bronchitis or pneumonia within two weeks of the apparent recovery as due to a fresh infection. If the baby was clear of infection for two weeks and then developed an infection (for diagnosis see the criteria mentioned later) this was counted as a fresh infection. Most of the babies were in the rooms for more than two weeks.

For babies who were admitted without signs of infection or were free of these for the preceding two weeks we used as our criterion for a hospital infection the following points:

1 If the baby developed an infection within the first three days in the hospital it was said to have been acquired before admission. Infections appearing in a "clean" baby after the third day were taken as hospital infections. This is an arbitrary rule, but it appears likely that the incubation period for the common cold is not more than three days.

2 If a baby showed any of the following signs—definite nasal discharge, a swollen red throat, postnasal drip, discharge from the ears or signs of bronchial or pulmonary disease—a diagnosis of a respiratory infection was made even when there was a normal tempera-

Fig 3—Cubicle in ultraviolet equipped room

ture. The prompt administration of sulfathiazole when symptoms of respiratory infection appeared may have been responsible for keeping the temperature at normal levels.

3 A temperature of 101 F or higher for one day or 100 F for two days in succession was taken as indicating a respiratory infection unless some other cause for this fever was discovered.

The following precautions were in force throughout the whole ward. All members of the staff wore masks made of one layer of fine flannelet, and they washed and applied a hand disinfectant (Dettol) which had been tested and found effective before attending a baby. Visitors were not allowed in the rooms and the floors were invariably cleaned by washing (no sweeping).

SERIES 1—Comparison of Infections Occurring in Ultraviolet Equipped Room and Open Control Rooms. The clinical results of the first nine months are shown in table 2.

USE OF ULTRAVIOLET RADIATION IN REDUCTION OF RESPIRATORY CROSS INFECTIONS

TORONTO

Following the installation in this hospital of a new operating room equipped with a battery of eight Westinghouse Sterilamps and an air changing system counts were made of the bacteria in the air of this room. Either of these agents reduced the number of air borne bacteria and the combination of the two was very effective.¹ This suggested the possibility of using similar means to reduce the number of cross infections in the infant ward.

In order to test the efficacy of various barriers to the spread of air borne bacteria, an experimental room was set up in the laboratory.² It consisted of a series of open door cubicles the entrances of which were 4 feet wide and 6 feet 2 inches high. Around the cubicle entrances, General Electric Ultraviolet Germicidal lamps (15 watt 18) were mounted with baffles in front and behind them so that a narrow curtain of ultraviolet radiation was thrown across the entrances. The number and arrangement of the lamps and the extent of the partitions at the sides of the cubicles were varied until a satisfactory combination was found. Their effectiveness was determined by spraying diluted cultures of *Bacillus prodigiosus* into the air and taking air samples with a Wells air centrifuge³ in various parts of the room. An air changing system was also installed and the best positions for the supply and exhaust vents were similarly determined.

Very few organisms passed from one cubicle to another with the following arrangements:

- 1 Six ultraviolet lamps mounted around the cubicle entrances
- 2 Partitions above the entrances extending to the ceiling
- 3 Side partitions from floor to ceiling
- 4 An air inlet near the floor at the back and an exhaust on the ceiling near the front of each cubicle

Shorter partitions and fewer lamps were less effective.⁴

RESULTS WITH ULTRAVIOLET RADIATION BARRIERS IN THE INFANT WARD

A room in the infant ward was then remodeled embodying the information obtained in this preliminary study. It provided accommodation for 6 infants under 6 months of age. The floor plan is shown in figure 1. Six ultraviolet lamps were mounted around the outer door which led into the vestibule used by the nurses,

6 more around the inner door which led into the room proper and 6 more around each of the cubicle entrances where there were no doors. The details of the positions of the lamps and reflectors are shown in figure 2. The room was heavily insulated but since there was no cooling apparatus in the system there were great variations in the temperature and humidity. A small basin with foot controlled taps was installed near the front of each cubicle. A cubicle is shown in figure 3.

Before this ward was put into use, experiments were carried out to check the efficiency of the radiation barrier. The Wells test for sanitary ventilation was used, with *B. prodigiosus* as the test organism, as described in a previous paper.² The efficiency of the lamps was found satisfactory when no air changing was used or when the air was changed four six or nine times an hour. Nine air changes an hour were therefore used.

When the apertures of the boxes in which the ultraviolet lamps were mounted were 3 inches wide, the bactericidal effect was excellent but the nurses suffered from burning of the skin. The apertures were therefore reduced to 1½ inches. They were still effective but no longer caused burning provided the inside walls of the

FIG. 1—Plan of room equipped with ultraviolet lamps. Arrows show direction of ultraviolet rays.

boxes were painted a dull black. The reflectors behind the lamps were made of aluminum.

Dr L R Koller of the Research Laboratory, General Electric Company, Schenectady, N Y, determined the amount of ultraviolet radiation in various parts of the room. At the back of the cubicle where the baby's cot was placed there was so little that it could not be measured. All members of the staff wore tinted glasses when working in this room. No other precautions were necessary for their protection. The nurses were instructed not to hold any infant near the doorway of the cubicle, and no case of burning or conjunctivitis occurred.

Four ultraviolet lamps, two on each side, were mounted in the air duct, which was 14 inches by 14 inches in cross section. This duct carried outside air into the room. The air passed the lamps at a rate of 218 linear feet a minute. To test the bactericidal power of these lamps, diluted broth cultures of *B. prodigiosus* were sprayed directly into the duct 2 feet ahead of the first lamps. Samples of duct air before and after passing the lamps were then taken simultaneously with two Wells centrifuges. The results obtained in one test are shown in table 1.

Similar results were obtained in five other tests and it was concluded that the air entering the room through

the air conditioning system was practically sterile. Previous Wells samples of outdoor air, taken at the level of the air intake, showed 2 to 3 organisms per cubic foot. No recirculated air was used in this room, but the ultraviolet lamps were mounted in the ducts in case there were some leaks in the system.

Fig 2—Mounting of ultraviolet lamps in posts between cubicles

To show whether this type of room was effective in practice we compared the incidence of respiratory cross infections among infants treated in it with that among similar infants in one of our usual unpartitioned rooms of the same size where the 6 cots were spaced around the walls. This room was ventilated by two windows and a transom over the door. This was called the first open control. The same physicians, nurses and maids worked in the two rooms. The nurses did not work elsewhere. After the babies in these two rooms were under observation for about five months, a second of the usual open rooms which accommodated 6 infants was used as another control. This was known as the second open control room. The babies in this room were nursed under the usual ward conditions, which meant frequent changes of nurses.

The admissions were divided between the three rooms, and most of the babies were "clean," that is free from respiratory or other infections, when admitted. If a baby

4th samples	13 580	368	
5th samples	17 500	420	

* The ultraviolet lamps were turned on immediately after the first samples were taken.

came in suffering from a respiratory disease which apparently cleared up, we did not consider the appearance of pyrexia, running ears, running nose, bronchitis or pneumonia within two weeks of the apparent recovery as due to a fresh infection. If the baby was clear of infection for two weeks and then developed an infection (for diagnosis see the criteria mentioned later), this was counted as a fresh infection. Most of the babies were in the rooms for more than two weeks.

For babies who were admitted without signs of infection or were free of these for the preceding two weeks, we used as our criterion for a hospital infection the following points:

1 If the baby developed an infection within the first three days in the hospital it was said to have been acquired before admission. Infections appearing in a "clean" baby after the third day were taken as hospital infections. This is an arbitrary rule, but it appears likely that the incubation period for the common cold is not more than three days.

2 If a baby showed any of the following signs—definite nasal discharge, a swollen, red throat, postnasal drip, discharge from the ears, or signs of bronchial or pulmonary disease—a diagnosis of a respiratory infection was made even when there was a normal tempera-

Fig 3—Cubicle in ultraviolet equipped room

ture. The prompt administration of sulfathiazole when symptoms of respiratory infection appeared may have been responsible for keeping the temperature at normal levels.

3 A temperature of 101 F or higher for one day or 100 F for two days in succession was taken as indicating a respiratory infection unless some other cause for this fever was discovered.

The following precautions were in force throughout the whole ward. All members of the staff wore masks made of one layer of fine flannel, and they washed and applied a hand disinfectant (Dettol) which had been tested and found effective before attending a baby. Visitors were not allowed in the rooms and the floors were invariably cleaned by washing (no sweeping).

SERIES 1—Comparison of Infections Occurring in Ultraviolet Equipped Room and Open Control Rooms.—The clinical results of the first nine months are shown in table 2.

These infections were also classified as to their severity. A child who had a temperature of 100 F for two successive days or of 101 F for one day, but no signs of respiratory infection was classified as having pyrexia, provided a thorough physical and laboratory examination failed to reveal any other cause for the

TABLE 2—Number of Infections in Ultraviolet Equipped and Open Control Rooms

Type of Room	Date	Number of Babies	Number of Babies Developing Infections	Percentage of Babies Developing Infections
Ultraviolet equipped (complete partitions and air changing)	11/13/39 to 7/29/40	46	8	17

Second open control	3/1/40 to 7/29/40	2	3	4	3

fever. If he had signs of nasopharyngitis but no fever the infection was called mild. Babies who developed bronchitis, pneumonia, running ears or prolonged high fevers associated with symptoms of nasopharyngitis were classified as having severe infections. Less severe infections were called moderate. The severity of the infections occurring in the first nine months is shown in table 3.

TABLE 4—Number of Infections in Ultraviolet Equipped Partitioned and Open Control Room (July 29, 1940 to June 20, 1941)

Type of Room	Number of Babies	Number of Babies Developing Infections	Percentage of Babies Developing Infections

TABLE 5—Severity of Infections in Ultraviolet Equipped, Partitioned and Open Control Rooms (July 29, 1940 to June 20, 1941)

Type of Room	Severe	Moderate	Mild	Pyrexia
Ultraviolet equipped (complete partitions and air changing)	2	2	3	5
Partitioned control	9	10	9	3
Second open control	9	15	10	2

In this series the infants treated in the open control rooms had three times as many infections as those in the room equipped with ultraviolet lamps, and more of these infections were severe.

SERIES 2—Comparison of Infections Occurring in the (1) Ultraviolet Equipped, (2) Partitioned and (3) Open Control Rooms.—The figures in table 3 show that the babies in the room equipped with ultraviolet lamps had definitely fewer infections than those treated

in the open control rooms. Possibly the fewer infections in the room equipped with ultraviolet lamps were due to the partitions which were also present, and, in order to rule this out, partitions running up 8 feet from the floor were put in the control room, thus dividing it into six cubicles. The partitions were not run to the ceiling, which was 10 feet high, because artificial ventilation was not provided. There was only one sink in this room. The nursing personnel was still the same in this room as in the room equipped with ultraviolet lamps. This was called the partitioned control room (fig. 4).

The number of infections occurring in the room equipped with ultraviolet lamps, the partitioned control and the second open control room during the next eleven months are shown in table 4 and the severity of these infections in table 5.

More than twice as many infections occurred among the control babies as among those in the room equipped with ultraviolet lamps. The babies in the partitioned con-

TABLE 6—Number of Infections* in Completely Partitioned Room with Air Conditioning, Partially Partitioned Room and Open Control Room (June 20, 1941 to April 6, 1942)

Type of Room	Number of Babies	Number of Babies Developing Infections	Percentage of Babies Developing Infections
Completely partitioned with air conditioning system	77	21	26
Partitioned control	71	26	37
Second open control	77	41	53

*During 1941-1942 fewer babies developed infections and hemolytic streptococci and pneumococci were isolated less frequently than during the year 1940-1941.

TABLE 7—Severity of Infections in Completely Partitioned Room with Air Conditioning, Partially Partitioned Room and Open Control Room (June 20, 1941 to April 6, 1942)

Type of Room	Severe	Moderate	Mild	Pyrexia
Completely partitioned with air conditioning	4	7	9	1
Partitioned control	4	10	5	2
Second open control	9	9	6	2

trol room developed fewer infections than those in the second open control room. Partitions alone therefore seem to play some part in preventing these hospital infections. There were also fewer severe and moderate infections among the babies in the room with the ultraviolet lamps.

SERIES 3—Comparison of Infections Occurring in Rooms with (1) Complete Partitions and Air Changing, (2) Partial Partitions and (3) No Partitions.—The room equipped with ultraviolet lamps also had complete partitions and an air changing system, both of which the control rooms lacked. In order to determine what part the complete partitions and air changing had in the results obtained the ultraviolet lamps were turned out and for the next nine months the number of infections occurring (1) in the room with complete partitions and air changing, (2) in the room with partial partitions and (3) in the second open control room were compared. The results are shown in table 6 and the severity of these infections in table 7.

There were slightly fewer infections occurring in the room with the complete partitions and the air changing system than in the partially partitioned and the second open control room. The difference however was slight.

The much better infection records of the babies in the room equipped with ultraviolet lamps, completely partitioned and air changed in the first two series were therefore almost entirely due to the ultraviolet radiation barriers.

EVIDENCE OF TRANSFER OF BACTERIA

1 *Bacteriologic Investigation of Upper Respiratory Tract*—Cultures of both tonsillar areas and the posterior pharyngeal wall were taken of each infant on admission and at weekly intervals throughout his stay in the hospital. Nasal cultures were also taken if any nasal discharge was present. Frequent cultures (usually daily) were taken of any baby who showed a rise in temperature or signs of infection of the upper respiratory tract. Cultures were also taken whenever possible of any other infected areas. The throats of the staff interns and nurses were swabbed as a routine once a week and whenever any respiratory infection developed.

The cultures were planted as soon as possible on moist human blood agar plates and incubated in an atmosphere of approximately 10 per cent carbon dioxide at 37.5 C for eighteen hours.⁵ Colonies suspected of being pneumococci or hemolytic streptococci were picked to fresh plates for isolation. The pneumococci were identified by the bile solubility test and typed by agglutination. The hemolytic streptococci which fell into group A (Lancefield⁶) were typed.⁷ To determine the group to which the strain belonged a method combining the techniques of Fuller⁸ and Brown⁹ was used. The typing serums¹⁰ were prepared according to the method of Mueller and Klise,¹¹ and the technique of Neisser¹² was used in the preparation of the antigen for agglutination.

Over a period of twenty-nine months cultures were taken of 674 babies. Sixty-seven strains of group A hemolytic streptococci (all but seven of which were typable) and one hundred and four strains of pneumococci were isolated. Cultures were taken of 291 members of the staff. These yielded seventy-five strains of group A hemolytic streptococci (all but seven of which were typable) and thirty strains of pneumococci. If the same type was recovered more than once from an individual it was counted as only one in the figures given. If a person had two different types of streptococci (always on different days) this was counted as two. In all, 4,356 cultures, the great majority of which were from throats, were taken.

The interns and nurses frequently carried hemolytic streptococci, usually without any symptoms of infection. These organisms were rarely recovered from cultures taken of the staff physicians. The carrier rate reached a peak during the late winter months and fell to

practically zero during the summer. The prevalent type of streptococcus differed from time to time. For instance, toward the end of 1940 type 3 was very common and types 12 and 5 were only occasionally encountered. In the next three months type 3 persisted with fair frequency but type 12 became very common. A few weeks later type 5 became very prevalent and type 12 almost disappeared. Both streptococci and pneumococci were carried for months without any apparent ill effects. One intern harbored hemolytic streptococcus type 10 from December 1939 until June 1940, when he left the hospital. Another intern carried pneumococcus type XIX for over a year. This was the most common type of pneumococcus encountered, and this intern may possibly have been the source of infection of 2 infants in the open control room.

Of the two hundred and seventy-six strains of group A hemolytic streptococci and pneumococci which were isolated, only eighteen were passed from baby to baby, from staff to baby or from baby to staff. Therefore according to our technique this is a rare occurrence. One such transfer occurred in the room equipped with ultra-

Fig. 4—Half of the partitioned control room.

violet lamps: two in the open control room, six in the partitioned control room (partial partitions) and nine in the second open control room. These are shown in table

TABLE 8—Transfer of Organisms

small that no definite conclusion is justifiable. Two instances of the transfer of organisms are reported here.

1 Baby F was admitted to the second open control room on October 7. No pathogenic organisms were found in his cultures until November 13 when a pure culture of type VI pneumococcus was isolated from his nose. The original source of this organism is not known. On November 20 Baby McC, who was in the same room, showed the presence of pneumococcus type VI in his throat culture. Baby McC had been in this room for six weeks and had never previously shown this organism. On November 26 Baby T who had been in the same room nearly a month developed an upper respiratory infection with type VI pneumococcus. Again this organism had not previously been found in his throat. The last two babies were evidently infected from Baby F.

2 Baby G was admitted on February 4 to the partitioned (partial partitions) control room and carried pneumococcus type XIX in his throat until his discharge on March 16. Baby H who had been in the same room for three weeks, developed a respiratory infection on February 6 and type XIX pneumococci were cultured from his throat on February 16 and 23 and March 2 which he apparently acquired from Baby G.

Fig. 5.—Room with ultraviolet irradiation of upper air.

Baby L, after more than five weeks in this room, contracted a type XIX infection on February 21, presumably from Baby G or Baby H.

In these studies 506 babies have been under observation and 188, or 37 per cent, of these contracted clinical infections. In only 16, or about 10 per cent of these, did we obtain evidence that these infections were due to bacteria. Assuming that the bacteriologic examinations were made sufficiently frequently, one would infer that virus infections were responsible for much of the disease of the upper respiratory tract encountered. Wells¹³ and also Andrews and Glover¹⁴ have studied experimental air borne virus infection in ferrets. Wells¹⁵ and Greene, Barenberg and Greenberg¹⁶ have described epidemics of virus diseases which were

apparently air borne and which were controlled by ultraviolet radiation of the air.

2 Presence of Organisms in the Air.—Counts were also made on numerous occasions from September 1940 to April 1942 of the number of bacteria in the air of the experimental rooms. Blood agar plates were exposed

TABLE 9.—Bacteria in Air (September 1940 to June 1941)

	Ultraviolet Equipped Room	Partitioned Control Room	Second Open Control Room
Blood agar plates number of colonies per plate (average)	109	258	264
Wells centrifuge number of colonies per 10 cu ft (average)	7	17	16

for varying periods of time simultaneously in all three rooms, and 10 cubic feet samples of air were taken with the Wells air centrifuge. The average counts are shown in tables 9 and 10.

In table 9 it is seen that the plates exposed in the control rooms showed more than twice as many organisms as those exposed in the room equipped with ultraviolet lamps. The Wells centrifuge counts also showed that the air in this room contained fewer organisms.

From table 10 it is evident that there is no significant difference between the air bacterial counts made in the completely partitioned room with air changing, the partially partitioned control room and the open control room.

RESULTS OF ULTRAVIOLET IRRADIATION OF THE UPPER AIR IN ROOMS

Encouraged by the previous results, a simpler method of indirect irradiation was tried out in three smaller rooms (12 by 8 by 10 feet). Three 36 inch 30 watt General Electric Germicidal lamps were hung in an aluminum reflector trough down the center of the room 3 feet 3 inches from the ceiling (see figure 5). The rays were deflected upward and provided a reservoir of clean air near the ceiling. No direct rays from the lamps reached the patients or the nurses and therefore precautions were not necessary to avoid burning of the skin or eyes. One of these rooms which usually contained four infants' cots or three larger cribs is shown

TABLE 10.—Bacteria in Air (June 1941 to April 1942)

	Completely Partitioned Room with Air Changing	Partially Partitioned Control Room	Second Open Control Room
Blood agar plates number of colonies per plate (average)	134	103	116
Wells centrifuge number of colonies per 10 cu ft (average)	25	68	76

in figure 5. One of these rooms was used exclusively for premature babies and will be discussed later. The other two rooms, with similar control rooms without the ultraviolet lamps, were used for babies up to 2 years of age. In these rooms it was not possible to admit only babies free from respiratory infection. Many were admitted with such infections and discharged within a short time. Unless the infant remained in the hospital for two weeks following his recovery from his respiratory infection he was not included in these records. The doors

and windows were frequently left open to improve the ventilation, and therefore the conditions in these rooms varied considerably. The clinical results in these rooms are shown in tables 11 and 12.

It is obvious that the ultraviolet lamps in these rooms did not reduce the spread of cross infection. The custom of leaving the corridor door open, resulting in a rapid movement of air past the ultraviolet lamps, may have been a factor in the unsatisfactory results.

Premature Rooms—A room used exclusively for 3 or less premature infants was also equipped with three General Electric Germicidal lamps as described. The temperature was kept between 77 and 85 F and the humidity at about 50 per cent. The doors and windows were always kept closed. A similar room without the lamps was used as a control. The same nurses worked in the two rooms. The number of infections occurring in these two rooms is shown in table 13.

TABLE 11—Number of Infections in Rooms with Indirect Irradiation and Control Rooms (March 1941 to March 1942)

Ultraviolet equipped with indirect irradiation	58	22	38
Control	64	22	34

TABLE 12—Severity of Infections in Rooms with Indirect Irradiation and Control Rooms (March 1941 to March 1942)

Type of Room	Severe	Moderate	Mild	Pyrexia
Ultraviolet equipped with indirect irradiation	6	11	2	7
Control	5	9	6	2

TABLE 13—Number of Infections Among Premature Babies in Rooms with Indirect Irradiation and Control Rooms (March 1941 to March 1942)

Type of Room	Number of Babies	Number of Babies Developing Infections	Percentage of Babies Developing Infections
Ultraviolet equipped with indirect irradiation	28	8	29
Control	24	12	50

The premature babies in the control room had nearly twice as many infections as those in the room equipped with ultraviolet lamps. Unfortunately a small number of babies were admitted to these cubicles during the year owing to their long stay in the hospital. While the numbers are not large enough to draw definite conclusions, this method of irradiation reduced considerably the spread of cross infections among the premature infants.

Routine throat cultures of the children in these three rooms and their controls were made from April 12 to June 26 1941. No bacteriologic evidence of the spread of pathogenic organisms from one to another was encountered. However, in February 1942, in a special investigation undertaken when 2 of 3 premature infants in the control room developed severe respiratory infections on the same day, throat cultures were taken of these infants and the staff attending them. Cultures from both sick babies showed hemolytic streptococcus type 3 and pneumococcus type VI was isolated from

1 of them as well. An intern attending these babies showed a heavy growth of hemolytic streptococcus type 3 in her throat culture at this time, and it may be presumed that the 2 infants acquired their streptococcal infection from her. A nurse who had come on duty in the room when the infants were showing the first signs of the infection had a slight sore throat when

TABLE 14—Severity of Infections Among Premature Babies in Rooms with Indirect Irradiation and Control Rooms (March 1941 to March 1942)

Type of Room	Severe	Moderate	Mild
Ultraviolet equipped with indirect irradiation	0	4	4
Control	4	4	4

cultures were taken five days later, and at this time many colonies of pneumococci type VI were isolated from her. The nurse may have been responsible for the pneumococcus type VI isolated from the infant or, conversely, she may have acquired it from him. The patient infected with only hemolytic streptococcus type 3 died.

BACTERIA IN THE AIR IN ROOMS WITH IRRADIATION OF THE UPPER AIR AND CONTROL ROOMS

The air in the irradiated rooms used for older infants contained as many bacteria as the air of the corresponding control rooms. In the rooms used for the premature infants the results are shown in table 15.

It is evident that the premature infants in the control rooms were exposed to three to four times as many air borne organisms as those in the irradiated rooms.

CONCLUSIONS

1 Infants treated in open six bed rooms or in a room with 8 foot partitions between the infants developed two to three times as many respiratory infections as babies in a room divided into cubicles with partitions running to the ceiling, a curtain of ultraviolet radiation across their entrances and an air changing system.

2 When the ultraviolet lamps were turned off and the progress of the babies in this room, which had complete partitions and an air changing system, was compared with that of other babies in the room with partial partitions, it was found that those in the latter room had only slightly more infections.

3 The curtains of ultraviolet radiation between the babies were therefore the major factors in the decided reduction of respiratory cross infections described in conclusion 1.

TABLE 15—Bacteria in Air in Rooms with Indirect Irradiation and Control Rooms (Premature Infants)

	Indirect Ultraviolet Irradiation	Control Room
Blood agar plates number of colonies per plate (average)	46	197
Wells centrifuge number of colonies per 10 cu ft (average)	22	63

4 Two hundred and seventy-six strains of group A hemolytic streptococci and pneumococci were recovered from the staff and the babies. In only 18 instances was the transfer of these organisms from patient to patient, from staff to patient or vice versa demonstrated.

5 Infants treated in rooms in which the upper air was irradiated showed approximately the same number of infections as babies treated in rooms similar but with-

out ultraviolet irradiation. The doors and windows in these rooms were frequently left open.

6. Premature infants treated in the regular premature room had nearly twice as many respiratory infections as similar infants in a room in which the upper air was irradiated. The doors and windows were kept closed in these rooms.

7. During the last two and one-half years the progress of 682 babies has been followed. Two hundred and fifty-eight or 38 per cent, have developed respiratory infections, many of which were mild.

VITAMIN B₁ THERAPY IN DIABETIC NEURITIS

WILLIAM NEEDLES, M.D.

NEW YORK

In a previous article¹ an attempt was made to determine the relationship, if any, between states of vitamin B₁ deficiency and diabetic neuritis. For this purpose a quantitative study of the vitamin B₁ content of the diet of patients with diabetic neuritis was made and found to be quite adequate as judged by the Cowgill formula. The evidence, clinical and pathologic, in favor of a vascular etiology in diabetic neuritis was mentioned, but the possibility that avitaminosis nevertheless played a role in producing the neuritic syndrome was not ruled out, since defective absorption or utilization of the ingested vitamin had still to be considered. Further evaluation of these factors it was stated at that time, was not feasible until tests for the metabolism of vitamin B₁ had been elaborated. Since then such a test has been introduced, and the results it has yielded will be discussed here.

The present study represents an attempt to tackle the problem of the relationship between avitaminosis and diabetic neuritis from a different angle, by observing the effects of vitamin B₁ therapy on the neurologic picture. Eleven cases were included at the outset, but in 4 of these cooperation was not sufficiently satisfactory to allow of regular and prolonged follow-up. A neurologic examination was made in each of the other 7 cases before therapy was instituted, then 10 to 15 mg of thiamine hydrochloride was given daily, and examinations were made again at intervals of a month. The average period of observation extended for five and a half months. The salient features of these cases are now presented.

REPORT OF CASES

CASE 1—A. L., a man aged 69, who entered the Mount Sinai Hospital on Jan. 28, 1941, had been found to have diabetes mellitus five years previously, and it had been controlled by dieting. In October 1940 he began to complain of weakness and numbness of the hands. Shortly thereafter progressive weakness of the legs and paresthesias in the feet set in. During the period from Oct. 3 to Nov. 12, 1941 he received, according to his private physician, 28 cc of thiamine hydrochloride half intravenously and half intramuscularly, each cubic centimeter equal to 0.0333 Gm., eight injections of concentrated liver extract, four injections of 1 cc of a vitamin B preparation, each cubic centimeter equal to 0.006 Gm of thiamine hydrochloride, 0.050 Gm of nicotinamide, 0.0001 Gm of riboflavin and 0.0001 Gm of vitamin B₆. Orally the patient received six tablets of yeast concentrate daily.

From the Neurological Service of Dr. I. S. Wechsler, Mount Sinai Hospital.

¹ Needles, William. Vitamin Studies in Cases of Diabetic Neuritis, Arch. Neurol. & Psychiat. 41: 1222 (June) 1939.

The physical examination disclosed cardiac enlargement and a systolic murmur at the apex of the heart. There was moderate sclerosis of the blood vessels. The blood pressure was 148 mm of mercury systolic and 88 diastolic.

Neurologic examination showed a shuffling gait and a positive Romberg sign, there was slight ataxia in all limbs, motor power was impaired in the upper and lower limbs, the arms and forearms showed some atrophy, the biceps, radial and ulnar reflexes and the patellar and ankle jerks were absent, the abdominal and cremasteric reflexes were absent, there were fibrillations in the muscles of the calf, pain, touch and temperature sensation were diminished over the lower limbs, the hands and forearms, vibration was diminished in the upper and lower limbs, and position sense was impaired in the fingers and toes. The muscles were tender to pressure.

The blood sugar was 230 mg per hundred cubic centimeters. The blood count and blood Wassermann reaction were negative. Free hydrochloric acid was present in the gastric analysis. The cerebrospinal fluid showed a 4 plus Pandy reaction and a total protein of 192 mg per hundred cubic centimeters, the dynamics were normal. Roentgen examination disclosed calcification in both posterior tibial arteries.

A tolerance test for vitamin B₁ was carried out but proved unsatisfactory owing to the fact that the patient had been receiving massive doses of the vitamin.

The condition was considered one of diabetic neuritis with some evidence of involvement of the spinal cord in addition.

On a diet of 100 Gm of carbohydrate, 80 Gm of protein and 80 Gm of fat the urine was free of dextrose.

He was given five tablets of yeast every four hours and 30 mg of thiamine hydrochloride intramuscularly every day. A week after this regimen there was diminution in tenderness of the muscles but no other change in the neurologic status. He continued to receive thiamine hydrochloride 30 mg a day orally after leaving the hospital. Neurologic examination at monthly intervals for a period of eight months disclosed no significant alteration in the findings. Weakness was more apparent and paresthesias persisted.

CASE 2—B. M., a woman aged 54, was observed in the diabetic clinic of the hospital in 1935, when diabetes mellitus was detected. Since that time the diabetes had been controlled by dietary regulation plus 10 or 20 units of insulin daily. She was admitted to the hospital in July 1938, at which time she showed moderate sclerosis of the blood vessels and a blood pressure of 110 systolic and 74 diastolic. The neurologic examination disclosed a somewhat broad based gait, there was some ataxia in the left lower limb, the right ankle jerk was feeble, the left ankle jerk, the hamstring reflexes and the reflexes in the upper limbs were not elicited, there was a glove and stocking distribution of hypalgesia, vibratory sense was absent at the knees and the left iliac crest, diminished at the feet and in the hands, position sense was impaired at the toes. She was considered to have diabetic neuritis.

When observed in the hospital in May 1939 her blood pressure was 180 systolic and 110 diastolic and she presented evidence of hypertensive and arteriosclerotic heart disease, as well as diabetes mellitus and diabetic neuritis.

A tolerance test for vitamin B₁ performed some time later yielded figures slightly below normal.

A neurologic examination in June 1941 disclosed the following positive findings. The deep reflexes in the upper limbs were absent, the ankle jerks were absent, even with reinforcement, there was bilateral calf tenderness, pain, touch and temperature sensation were diminished below the middle of the legs, vibratory sense was diminished at the feet and knees and absent at the iliac crests. Subjectively the patient complained of pains in the legs and a sensation of heaviness in the feet and hands. She was placed on the usual amounts of thiamine hydrochloride.

Periodic examination up to December 1941 showed no essential changes in the objective neurologic findings. The patient stated that she felt stronger generally and that the paresthesias were less troublesome. Tenderness of the calves persisted and was well defined.

CASE 3—M C, a woman aged 54, was discovered to be suffering from diabetes mellitus in October 1940. The diabetes had subsequently been controlled by dietary measures. A sensation of heaviness in the hands had appeared about six months prior to October 1940. The physical examination showed a blood pressure of 170 systolic and 100 diastolic, the second aortic sound was accentuated. Roentgen examination disclosed several calcified plaques in the right posterior tibial artery. A tolerance test for vitamin B₁ yielded normal results.

Neurologic examination in April 1941 showed that tenderness of the calves was present, the knee jerks were depressed but fairly lively after reinforcement, the ankle jerks were absent even with reinforcement, pain, touch and temperature sensation were diminished over the lower two thirds of the legs and the feet and over the hands, vibratory sensation was diminished at the feet and knees.

Therapy with thiamine hydrochloride was instituted June 1941 and the neurologic status was checked periodically up to December 1941. The objective findings remained in statu quo in all essential details, tenderness of the calves was diminished, however, and the paresthesias were less apparent.

CASE 4—S B, a woman aged 38, observed at the Mount Sinai Hospital in January 1941, had been suffering for several years from diabetes mellitus, which had been controlled by dietary measures. For the past year she had developed cramps in the legs when walking and tingling sensations in the toes. There was also a history of "hysterical" attacks of crying and screaming, and of nervousness since 1936. In 1940 menopausal symptoms had set in. The general physical examination at this time disclosed no significant findings. The patient was, however, emotionally unstable and very querulous. The neurologic examination showed absence of deep reflexes in the lower limbs, vibratory sense was diminished up to a level of the midlumbar spine. The blood sugar determination was 175 mg per hundred cubic centimeters. The urine was free of dextrose. The cerebrospinal fluid was normal. Free hydrochloric acid was present in the gastric contents.

A tolerance test for vitamin B₁ showed normal excretion.

The diabetes mellitus was controlled by a diet of 150 Gm of carbohydrate, 60 of protein and 80 of fat, with 20 units of insulin daily. Neurologic examination in June 1941 showed absence of the knee and ankle jerks, vibratory sensation was lost at and below the iliac crests, diminished at the hands and wrists, moderate tenderness of the calf muscles was present. Cutaneous sensibility was difficult to evaluate, there being an inconstant glove and stocking type of diminution, there was a tendency to veer in walking, and the Romberg test was positive when the eyes were closed. In view of the history of a psychoneurotic disorder and the reaction of the patient during the examination, a psychogenic basis for some of the abnormal findings could not be ruled out.

Treatment with thiamine hydrochloride was instituted and the patient was observed at monthly intervals up to January 1942. The neurologic findings, those which allowed of a psychogenic interpretation as well as those that did not, remained unaltered. Tenderness of the calf muscles persisted as heretofore. The paresthesias continued, but in a milder form.

CASE 5—S S, a woman aged 22 who developed diabetes mellitus at the age of 8 years, had been under constant observation at the hospital since that time. The diabetes was originally controlled by a diet of 65 Gm of protein and 100 Gm of fat. Later she received 100 Gm of carbohydrate, 60 Gm of protein and 60 Gm of fat with 50 units of insulin daily. She was admitted to the hospital in December 1939 after a convulsive episode.

The general physical examination disclosed no significant findings. The blood pressure was 120 systolic and 90 diastolic. The blood count was normal. The urine contained 6 per cent of dextrose. The blood sugar was 155 mg per hundred cubic centimeters. The spinal fluid and the electroencephalogram were normal. Roentgen study of the skull was normal. Neurologic examination showed absence of the right and diminution of the left ankle jerk. The knee jerks were diminished, the pupils were irregular, but equal and reactive. The fundi showed a few retinal hemorrhages and evidence of diabetic choroiditis.

The neurologic examination four months later showed the ankle jerks to be depressed and the knee jerks present only with reinforcement. In November 1940 the patient complained of tingling sensations in the hands and feet.

A tolerance test for vitamin B₁ showed normal figures.

Neurologic examination in June 1941 showed that the left knee jerk and both ankle jerks were absent, even with reinforcement, the right knee jerk was absent but fairly active with reinforcement, there was tenderness of the calf muscles, the right pupil was ovoid and was feeble in response to light stimulation.

Therapy with thiamine hydrochloride was instituted and the patient observed until October 1941 after which time she failed to cooperate. When last examined she did not feel subjectively improved. Tenderness of the calf muscles was exquisite. The paresthesias persisted. The knee and ankle jerks were absent, even with reinforcement. Pain, touch and temperature sensations were diminished below the ankles, vibratory sensation was diminished at the ankles and toes. There was evidence of progression of the neurologic syndrome during the period of thiamine hydrochloride therapy.

CASE 6—M L, a woman aged 58 was discovered to have diabetes mellitus in June 1941. For the preceding year she had suffered from weakness of the legs, paresthesias in the feet and pain in the calf muscles on walking. The general physical examination disclosed enlargement of the heart toward the left and a systolic murmur at the apical and aortic regions. The blood pressure was 182 systolic and 110 diastolic. A blood Wassermann test was negative. The diabetes was controlled by a diet of 120 Gm of carbohydrate, 80 Gm of protein and 100 Gm of fat with 10 units of insulin daily.

Neurologic examination in July 1941 showed that the knee jerks were decidedly depressed, even with reinforcement, the ankle jerks were feebly obtained but fairly normal with reinforcement. Vibratory sensation was diminished at the hands, feet and knees. The calf muscles were exquisitely tender. The patient was observed under a regimen of thiamine hydrochloride until December 1941. The paresthesias had disappeared, tenderness of the calf muscles was diminished, the reflex and objective sensory disturbances remained unaffected.

CASE 7—W B, a man aged 47, admitted to the Mount Sinai Hospital in September 1941, had been discovered to have diabetes mellitus eighteen months prior, and it had been controlled by a diet of 180 Gm of carbohydrate, 80 Gm of protein and 80 Gm of fat with 40 units of protamine zinc insulin every morning. Since July 1941 he had been troubled with pains in the legs and peculiar sensations in the feet and hands. The physical examination showed peripheral arteriosclerosis, there was a systolic apical murmur, the blood pressure was 110 systolic and 80 diastolic, the right dorsalis pedis artery was not palpable, there was bilateral purulent otitis media. Neurologic examination disclosed the middle ear type of deafness bilaterally, all deep reflexes were absent or greatly depressed, the abdominal and cremasteric reflexes were absent, there was tenderness of the calf muscles, hypalgesia of the glove and stocking distribution was present, vibratory sense was diminished in the lower limbs, diabetic retinopathy was evident in the fundi. The blood count, the blood Wassermann reaction and the cerebrospinal fluid findings were normal. The urine showed a trace of dextrose. The blood sugar was 85 mg per hundred cubic centimeters.

Soon after admission to the hospital he was given 50 mg of thiamine hydrochloride intramuscularly every day. The neurologic condition after two weeks of this regimen showed no improvement. Oral administration of the vitamin was continued after his discharge from the hospital. In November 1941 he showed no improvement either subjectively or objectively. Pain and weakness of the limbs persisted, the deep reflexes were absent and the cutaneous and vibratory sensory disturbances remained unaltered.

Four other cases could not be utilized because of faulty cooperation. In two of them the tolerance test for vitamin B₁ was carried out and in each case the results were normal.

COMMENT

A survey of this group of cases leads to the conclusion that no amelioration of the neurologic syndrome was demonstrable objectively. In 2 of the 7 cases there was an increase in the neurologic involvement despite therapy with thiamine hydrochloride. Subjective improvement apparently occurred in 4 of the cases in that the weakness and the paresthesias remitted. Tenderness of the muscles of the calf was far from uniformly relieved.

These findings are distinctly at variance with those reported by Fein, Ralli and Jolliffe² after a similar study. These observers found significant improvement in all of their 9 cases, tenderness of the calf disappeared, the ankle jerks were restored and vibratory sensation reappeared following therapy with thiamine hydrochloride. They therefore concluded that B_1 avitaminosis was the responsible factor in the production of the neuritic syndrome. Quantitative estimation of the vitamin B_1 content of the diet of their patients showed it to be well above the minimal requirement substantiating in this respect my original findings. However, the therapeutic response of their patients to thiamine leads them to postulate that their patients indulged in dietary indiscretions to the degree that the adequate vitamin-caloric ratio no longer obtained. It should be pointed out that they concede at least a contributory role in the pathogenesis to vascular disease when they state that, owing to compromise of the blood supply to the peripheral nerves, a greater intake of vitamins might be needed to supply the tissues adequately than would otherwise be the case.

In seeking a possible explanation for the response to thiamine hydrochloride in their cases and the failure of the response in the present series, one feature claims attention. The degree of neurologic involvement was slighter in their group. In none of their cases were the knee jerks affected, in none were there significant disturbances of the cutaneous sensory modalities. One might contend that in these instances the disease process was milder, while in my group of cases it had produced irreversible and irreparable damage. The situation would then be similar to that in subacute combined degeneration of the spinal cord in pernicious anemia, in which therapy with liver is much more effective in preventing the onset of the condition than in clearing up neurologic signs that have already set in. This explanation would not, however, account for the progression that occurred in 2 cases of the series in which ample doses of thiamine were administered.

There are certain other considerations moreover, which militate against an avitaminotic etiology in diabetic neuritis. Pollack, Ellenberg and Dolger³ have recently evolved a tolerance test for vitamin B_1 . They established that normally, after an intramuscular injection of 0.001 Gm of thiamine hydrochloride, over 180 micrograms is excreted in the urine within four hours while in cases of vitamin deficiency less than this amount is excreted. The excretion rate of patients with diabetes mellitus in the vast majority of instances was normal; in only 13 out of 139 cases was the excretion level below normal, the percentage of cases with low excretion levels was smaller than in a large group of unselected patients. A normal level of excretion is

indicative of adequate absorption and utilization of the vitamin.⁴ At this point it should be recalled that in 6 of my cases a tolerance test for vitamin B_1 was carried out. In 1 the excretion was found slightly below normal, in the others normal figures were obtained.

Street and his co-workers⁵ found that a diet chronically deficient in vitamin B_1 will produce neurologic changes that are irreversible. They maintained dogs for three hundred and fifty-four days on a subminimal, partially deficient diet until neurologic signs of peripheral neuritis developed. They then administered large doses of vitamin B_1 for a month. No significant changes occurred. Postmortem examination showed involvement of the peripheral nerves and anterior roots as well as of the posterior column of the spinal cord. They draw a distinction between acute and chronic disease from vitamin deficiency; in the former vitamin therapy restores the animal to a normal condition within a few hours, presumably because the nervous disorder is merely functional, in the latter, permanent irremediable damage to the nervous structures results. Since dietary deficiency in man is much more likely to be partial than complete, they consider an experimental study of partial deficiency to resemble more closely the condition in man. This would certainly appear to be applicable to cases of diabetic neuritis, in which no sudden curtailment of diet occurs. So that, theoretically at least no improvement of a diabetic neuritis presumably due to B_1 avitaminosis is to be expected from vitamin therapy.

The conclusions to be drawn from this study may appear unduly nihilistic. Hence I would add that in the present state of our knowledge no inferences drawn from the laboratory, no matter how cogent they may appear, should outweigh empirical findings at the bedside. Further study of diabetic neuritis particularly in the less advanced phase and with the benefit of the recently devised tests for vitamin B_1 metabolism, should establish whether avitaminosis is a decisive factor, operating in all cases, or merely a coincidental factor to be found in some cases.

CONCLUSIONS

Seven cases of diabetic neuritis were studied before and after therapy with thiamine hydrochloride. In none was any improvement noted, in 2 progression of the neurologic syndrome occurred.

Evidence indicates that in diabetic neuritis the metabolism of vitamin B_1 does not vary significantly from the normal.

Digestive Time of Food—The digestion time of various foods is of the greatest importance because clinically many diseases manifest themselves by a delay or definite arrest in the evacuation of food from the stomach. We can ascertain much regarding motor function by gastric analysis. Not only do we observe the degree of food chymification as an index of gastric peristaltic function, but we also determine the evacuation time as a measure of the length of time necessary for the stomach to do its work. We can do this in two ways, either we can perform a complete fractional analysis throughout the entire digestion period or we can pass the tube at a stated interval after which a certain meal is normally digested noting whether or not the stomach is empty or whether there is an actual delay.—Rehfuess, Martin E. *Indigestion Its Diagnosis and Management*. STUDIES ON THE ACTION OF
QUINIDINE IN MANII INTRAMUSCULAR ADMINISTRATION OF A SOLUBLE
PREPARATION OF QUINIDINE IN THE TREAT-
MENT OF ACUTE CARDIAC ARRHYTHMIASMELVIN I STURNICK, MD
JOSEPH E F RISEMAN, MD
AND
ELLIOT L SAGALL, MD
BOSTON

Soluble preparations of quinidine sulfate for parenteral administration have not been readily available. Quinine dihydrochloride has been administered intramuscularly or intravenously.¹ Dilute solutions of quinidine sulfate in dextrose or water² and even suspensions of quinidine sulfate tablets in hot water and hydrochloric acid³ have been administered in emergencies, but there are important objections to these procedures.

The necessity for a soluble preparation of quinidine suitable for parenteral administration in treating acute cardiac arrhythmias is obvious, especially when the abnormal rhythm is associated with vomiting, collapse, unconsciousness or other conditions in which absorption from the gastrointestinal tract is uncertain or delayed. A prolonged search of the American market for a soluble preparation has been unsuccessful. The Cinchona Products Institute, however, suggested that such a product might be obtained by adding urea and antipyrine to quinidine hydrochloride according to the following formula:

	Gm or Cc
Quinidine hydrochloride	15
Antipyrine	15
Urea	20
Distilled water	to make 100

So far as we have been able to ascertain, this preparation has not been used, although a similar solution of quinine has been employed in the treatment of specific infections.⁴

No difficulty was encountered in making this solution and, in contrast to other soluble forms of quinidine, the ingredients are readily available. The mixture results in a clear colorless solution with 0.15 Gm of quinidine hydrochloride in each cubic centimeter. Sterilization is best carried out by passage through a Berkefeld filter, after which the solution can be stored in ampules or rubber stoppered bottles available for emergency use. After several months this solution, like all quinine solutions, turns brown. This change in color occurs even when protected from the light, it is said to be due to the formation of a relatively small

amount of decomposition products and is not accompanied by any discernible change of potency or by adverse reactions.

The speed of response to intramuscular administration of this preparation in human subjects has been reported.⁵ Our purpose in the present communication is to report observations in the treatment of 24 episodes of acute arrhythmias in a series of 20 consecutive patients.

MATERIAL AND METHODS

The clinical characteristics of the patients studied are presented in the accompanying table. Electrocardiographic tracings confirmed the diagnosis in each instance before therapy was instituted. The response to treatment was gaged by the change in the heart rate at the apex, by disappearance of shock and other symptoms associated with the arrhythmias by improvement in the patient's general condition and, whenever indicated, by repeated electrocardiographic tracings. Blood pressure determinations were taken at frequent intervals.

Medication was administered intragluteally or in the lateral aspect of the thigh. The initial dose was 0.15 Gm in 1 instance, 0.3 to 0.45 Gm in 11 instances, 0.6 Gm in 9, 0.75 Gm in 2 and 1.05 Gm in 1. In accord with the studies previously reported,⁵ the response to this initial dose was observed for one and one-half to two and one-half hours. If the rhythm failed to revert to normal during this period, additional medication was administered. The size of subsequent doses was increased if only a slight or moderate response to the initial dose was observed.

RESULTS

The rhythm reverted to normal within three hours after medication in 15 of 24 instances (13 of 20 patients). In each instance the clinical response indicated that conversion to normal rhythm was due to this medication. This group included 5 instances of ventricular tachycardia, 9 of auricular fibrillation and 1 of auricular tachycardia. Nine of the patients had arteriosclerotic heart disease, 2 had rheumatic heart disease, 1 was a toxic reaction to medication and 1 was a postoperative reaction.

Causes of Failure to Respond—In the remaining 9 instances the condition failed to respond to therapy. Three of these patients had sinoauricular tachycardia (cases 4, 5 and 11), no response to quinidine was expected in these cases. One patient with nodal tachycardia (case 9) died of pulmonary edema before the drug had had sufficient time to exert its beneficial action. In 1 instance (case 12) it is probable that the medication was repeated too infrequently to result in adequate cumulative effect. In 3 cases conversion to normal rhythm took place during the night and the time of transition was not observed. The remaining case (20) failed to respond to quinidine despite adequate dosage.

Optimum Size of Initial Dose—The rhythm of only 1 of the 8 patients who received an initial dose of less than 0.45 Gm reverted to normal within two hours after the administration of the one dose. The rhythm of 1 of 3 patients who received an initial dose of 0.45 Gm reverted to normal on two occasions following this dose. The rhythm of 2 of the 9 patients who received an im-

tial dose of 0.6 Gm or more was converted to normal by this amount. Of the 15 patients whose rhythm reverted to normal within three hours after the administration of quinidine, 5 did not need more than a single injection. Three of these 5 patients received 0.6 to 0.75

Gm and the other 2 patients received 0.33 and 0.45 Gm. It appears, therefore, that an initial injection of 0.45 to 0.6 Gm is advisable.

Toxic Effects—When the medication was given intragluteally or in the lateral aspect of the thigh, pain

(case 20) had diarrhea after receiving 3.6 Gm within seven hours. There were no instances of tinnitus, dermatitis or other toxic manifestations following medication.

Mortality—Six patients died during their hospital stay. In no instances could death be attributed to the quinidine therapy. All of these patients were moribund when therapy was started. Four died twenty minutes to four days after conversion of the rhythm to normal (cases 14, 16, 7 and 10). 2 died without control of the arrhythmia (cases 9 and 20).

The prognosis for life when therapy was started was very poor in 14 instances, doubtful in 5 and favorable in 5. In 4, therapy appeared to be a life saving measure (cases 1, 15, 3 and 16). In 11 other instances therapy had a favorable influence on the symptoms and course of the disease.

Comparison of Intramuscular with Oral and Intravenous Administration—Four patients were vomiting at the time therapy was started, and it was obviously impossible to give medication by mouth.

Two patients previously had been treated for similar episodes by oral quinidine or intravenous quinine. In 1 patient (case 1) ventricular tachycardia was converted to normal rhythm twenty minutes after the fifth dose of quinidine sulfate by mouth (0.3, 0.5, 0.6, 0.6 and 0.6 Gm), a total of 2.63 Gm had been given within eight hours. Twelve days later a recurrence of ventricular tachycardia was converted to normal rhythm one hour and forty minutes after the third intramuscular injection. Quinidine was injected at intervals of two to three hours (0.6, 0.86 and 1 Gm), a total of 2.46 Gm was given within five hours and twenty minutes.

Patient 12 had numerous paroxysms of auricular fibrillation. On two occasions these were treated successfully with quinidine sulfate by mouth (0.3 Gm every two hours for five doses), but each time the patient had a severe diarrhea and was unable to continue with a maintenance dose of quinidine. On two other occasions quinine dihydrochloride was given intravenously (1.2 Gm given in the course of four hours and 3.1 Gm over a period of sixteen hours). In both instances the rhythm was controlled, but tinnitus and other severe toxic reactions to the drug developed.

Intramuscular therapy was used on two occasions. In 1 instance 0.73 Gm was given in two doses thirty-five minutes apart. The rhythm reverted to normal one hour after the second dose. On the second occasion 2.7 Gm was given in three divided doses at intervals of four hours. The rhythm became normal within twelve hours after the last dose. On neither occasion did the patient experience any gastrointestinal or other symptoms.

Two patients received injectable quinidine on more than one occasion. On one occasion (case 8) auricular fibrillation reverted to normal rhythm two hours after a total of 0.45 Gm had been administered intramuscularly in two divided doses, and on two other occasions the rhythm reverted one hour after a single intramuscular dose of 0.45 Gm. The rhythm of a second patient (case 12) reverted one hour after a total of 0.75 Gm was given intramuscularly in two divided doses thirty-five minutes apart, while on the second occasion it failed to revert after a total of 2.7 Gm in three divided doses given at intervals of four hours.

A third patient (case 7 and 7a) was treated successfully on one occasion for paroxysmal auricular fibrillation and at another time for paroxysmal ventricular tachycardia. A total of 1.65 Gm was given for the first arrhythmia in three divided doses over a period of four hours and twenty-five minutes while in the latter instance a total of 2.5 Gm was given in two divided doses one hour and forty-five minutes apart.

It is evident that intramuscular quinidine is at least as effective as oral or intravenous preparations and is less likely to cause toxic symptoms. Intramuscular administration is of obvious value when the patient is vomiting or is in collapse and oral therapy is unsatisfactory. Undoubtedly other more soluble preparations of quinidine will be made available in the future. One such preparation, quinidine hydrochloride dissolved in propylene glycol, has been suggested by Dr. Mark Altschule and Mr. Harry Brass and is being investigated at the present time. The preparation of quinidine hydrochloride with urea and antipyrine used in these studies has the advantage of being available at the present moment and of proved value without untoward side reactions.

SUMMARY AND CONCLUSIONS

1. A soluble preparation of quinidine suitable for parenteral administration containing 0.15 Gm in each cubic centimeter can be made by the addition of urea and antipyrine to quinidine hydrochloride. The preparation of this solution is not difficult and the ingredients are readily available. Since this injectable quinidine can be stored in ampules, it is of practical value in the emergency treatment of acute cardiac arrhythmias.

2. Twenty-four episodes of acute cardiac arrhythmias in a series of 20 patients were treated by the intramuscular administration of this preparation. In 15 instances (13 patients) the rhythm was converted to normal. In 3 additional instances conversion to normal was probably due to this therapy. In 1 instance the dose used was too small. In the remaining 5 instances the drug failed to control the abnormal rhythm. Three of the 5 instances were attacks of sinoauricular tachycardia.

3. Toxic reaction to the drug (mild diarrhea) was experienced by only 1 patient. No local reactions were encountered.

4. The following appears to be a practical method for using the drug in the treatment of acute arrhythmias.

An initial dose of 0.45 to 0.6 Gm should be given intramuscularly.

The response to each dose should be observed for one and one-half to two and one-half hours. If conversion to normal rhythm does not occur in that time, additional medication is indicated.

A favorable response consists in definite slowing of the apical heart rate, a rise in blood pressure to above the shock level, decrease in symptoms or striking improvement in the patient's general condition. In such instances the initial dose may be repeated. If a favorable response is not observed, it is advisable to increase the size of the dose.

5. Injectable quinidine can be used whenever oral quinidine therapy is advisable. It is especially indicated when absorption from the gastrointestinal tract may be delayed or unreliable (vomiting, shock and the like) and when rapid therapeutic action is desired.

COUNTY ACCREDITATION PLAN FOR
TUBERCULOSIS CONTROL

J. ARTHUR MYERS, MD

MINNEAPOLIS

For a number of years the members of the Committee on Tuberculosis of the Minnesota State Medical Association have felt that tuberculosis has been reduced to such a degree in this state and the physician's commitment is now such that the time is ripe for an all out campaign against this disease.

In 1940 a questionnaire was sent to each of the state medical associations to determine what was being done in other states. We were somewhat surprised to learn that thirteen of the state medical associations did not have a tuberculosis committee in fifteen states such committees have been in existence for three years or less and in four states for three to five years, in the remainder the committees had been in existence for more than five years. In three states the tuberculosis work was done by a subcommittee of a public health committee. In most of the states the activities of the tuberculosis committees were of a general nature, and in less than six states was there an adequate program. However, in Hawaii and Alaska good programs were under way, but the best was found in Puerto Rico. Thus it appears that our state medical associations, as such have done little by way of organization or control tuberculosis. Our committee is of the opinion that state medical associations everywhere should play a leading role in tuberculosis control.

Our members surveyed the field with reference to the various methods of approach. We were cognizant of the fact that there are enthusiastic advocates for the examination of certain groups in a given community. For example, there are those who maintain that the examination of children is adequate, but there is abundant evidence to show that children prior to 12 years rarely have contagious pulmonary tuberculosis, therefore from the standpoint of actually finding cases of this type of the disease, not enough exist to justify the effort and expense. The administration of the tuberculin test to children of all ages has been found of great value for two reasons. First, whenever a child reacts characteristically to tuberculin there can be no doubt that he has had direct or indirect contact with a case of contagious tuberculosis, and a search for such cases among the reacting children's adult associates is always profitable if it is carefully done, despite the fact that not all sources are found in this manner. Second, every child who reacts to tuberculin should have routine, annual examinations when adulthood is reached.

In the high school age group the same facts obtain as in the grade school period, except that the reinfection type of chronic pulmonary tuberculosis becomes more prevalent, and therefore all high school students who react to tuberculin should have annual examinations for clinical pulmonary tuberculosis.

While the examination of preschool, grade and high school children as outlined is of great value, it is obvious that this alone is inadequate, since there is often contagious tuberculosis in homes where there are no children.

Another method that has been emphasized consists in the examination of the contacts of patients with contagious tuberculosis. By this method one procures from the health department the names and addresses of all persons reported as having clinical tuberculosis, and to this list are added the names of all persons whose death certificates state that they have died from tuberculosis during the past five or ten years. An attempt is then made to examine the contacts of the current patients as well as of those who have died from the disease. This our committee recognized as a good case finding method, but it was thoroughly cognizant of the fact that one could never hope to control the disease completely in a community by this method alone, because there are many persons who die from chronic pulmonary tuberculosis whose disease is first reported to the health department by death certificate. In some of our states this is true in as many as one fourth to one half of the cases. Thus, many persons with contagious tuberculosis are permitted to do all the harm that is possible, by way of dissemination of tubercle bacilli, without our knowledge of the existence of their disease. Obviously, therefore, the examination of so-called contacts only is not adequate. Moreover, there is a significant number of persons who have contagious tuberculosis and die from other major conditions and the tuberculosis is never recognized. Thus death certificates by no means reveal all those persons who have contagious tuberculosis at the time of death. Thus the persons exposed to such individuals cannot be included by the method of examining contacts only.

Other special groups, such as the personnel of school systems and hospitals, industrial workers, relief clients, pregnant women and elderly persons, may be examined with great advantage. As laudable as is such an undertaking in any community, it would not suffice to control tuberculosis adequately, since many contagious cases may exist among the groups not examined.

Our committee found that many physicians have been misled by the method that has heretofore been used in determining the cost of finding cases of tuberculosis. For example, if a thousand university students were examined and only 0.5 per cent, that is, 5 individuals, were found with demonstrable reinfection type of pulmonary lesions, the entire cost of the thousand examinations was charged to these 5 cases. To us this does not seem to be the proper conception of the cost of case finding, since if 20 per cent, or 200, of the thousand students react to tuberculin, one has, in the strict sense of the word, found 200 cases of tuberculosis. Moreover the cost of examining the entire thousand should not be charged only to the 200 cases, for it is of great value to know that the remaining 800 do not have tuberculosis in any stage of its development.

Every physician knows that tuberculosis is contagious and obviously, all contacts of contagious cases should be examined not only, once but periodically as long as no clinical disease is found. This would be an ideal method if all contagious cases were known. Our committee members came to the conclusion that the only way to find all cases of tuberculosis is to examine every

Read before the joint session of the Mississippi Valley Conference on Tuberculosis and the Mississippi Valley Trudeau Society in Chicago Sept. 17, 1942.

Other members of the committee are Drs. R. A. Barr, L. V. Berghs, H. A. Burns, S. S. Cohen, K. A. Danielson, C. F. Ewing, W. H. Feldman, L. H. Flancher, E. K. Geer, G. A. Hedberg, A. J. Henderson, R. R. Hendrickson, W. S. Hitchings, E. A. Mejerding, K. H. Pfuetez, C. L. Scofield, S. A. Slater and B. B. Souster.

one in the entire community or political division, for often this disease is found where it is least expected. Every community should determine its entire tuberculosis situation, it does not suffice to know only about those who have entered on the consumptive stage in the development of the disease. It is important to know how many and who are entirely free from tubercle bacilli, how many and who have these organisms in their bodies and those in the latter group who have or later develop demonstrable clinical disease that requires treatment.

Our committee members were cognizant of the fact that to undertake a complete campaign against tuberculosis in an entire state as an initial program was too great a step for one time. While this was recommended to all the medical societies in the state as a procedure to take under advisement, it was decided that a county should be selected where there was every reason to hope that an all out campaign would not only be instituted but would be completed by the local physicians and their allies. This county would become the demonstration center in which the various details of the campaign could be tested and which would later serve as a laboratory for the physicians of the other counties. Numerous counties were considered, and Meeker was chosen for several reasons, some of which are as follows:

- 1 The first mass tuberculin testing of human beings done in Minnesota was carried on in Meeker County in 1912 by the late Dr. H. G. Lampson of the Minnesota State Board of Health.
- 2 This county was the first in Minnesota to institute a county wide tuberculin testing campaign of its cattle. This program, which was begun in 1923, met with much opposition, in fact, it was carried to the Minnesota courts two or three times and finally to the United States Supreme Court. However, those in charge of the campaign were successful and the county was accredited in 1925. The other counties profited by this example and in 1935 all the counties were accredited and, thus, the entire state became an accredited area.
- 3 Meeker County still has a relatively high tuberculosis mortality rate and, thus, there existed an opportunity to demonstrate what can be done in controlling the disease in man.
- 4 The medical profession in this county is composed, without exception, of physicians with a modern point of view and a strong desire to control the disease in man at the earliest possible time.

The next step was to determine whether the local medical profession of Meeker County would be willing to undertake such a program. On Aug. 19, 1940 members of our committee met with the physicians in Meeker County. They were found to be unanimous in their desire to make their county the laboratory center for the state. Their chief interest was to control the disease as soon as possible. For several months thereafter the state committee met with the Meeker County Society, and after much discussion and careful consideration of various methods of procedure it was decided that the program should consist of the following procedures:

- 1 The tuberculin test should be offered to the entire population of 19,000 citizens.
- 2 X-ray film inspections of the chests should be made of all persons who reacted to tuberculin.

- 3 Careful clinical and laboratory examinations should be made of those whose x-ray films revealed shadows that might be caused by clinical pulmonary tuberculosis.

- 4 Arrangements should be made for adequate treatment and isolation, when necessary, of all persons found to have this type of tuberculosis.

It was decided that the intracutaneous (Mantoux) method of administering tuberculin is superior to all others and that Koch's old tuberculin should be employed since it could be supplied gratis, in the proper dilution to the physicians of the county, by the state department of health. Moreover, the local physicians agreed to administer and interpret the tuberculin test to every citizen of the county without any financial remuneration.

All the various methods of making x-ray film inspections of the chest were carefully considered by the local physicians and the members of the state committee. It was decided to use paper film of standard size in cut sheets because there was an abundance of evidence available to show that this film is equal to celluloid film in the detection of pulmonary lesions. Moreover, this film could be procured at a good deal less than one-half the cost of celluloid film. While the paper film is considerably more expensive than the miniature films (35 mm. and 4 by 5 inch) used in making photofluorograms, these miniature films were not considered equal to the paper film of standard size. Moreover, no outlay for new x-ray equipment was necessary for exposure and development of the paper film.

X-ray equipment was found to be available in the offices of four physicians and one hospital, and it was agreed that all x-ray work would be done with these five machines. The local physicians were most generous in volunteering to expose and develop the films with no financial consideration, but it was understood that the state committee would attempt to procure funds for the purchase of the unexposed films. The members of the committee were desirous that all work be done by the local physicians, several of whom were proficient in describing shadows seen on x-ray films. Therefore all films would be described by local physicians who were thoroughly cognizant of the fact that final diagnosis from x-ray shadows alone is a physical impossibility. In other words, the physicians of Meeker County looked on the x-ray film inspection only as a screen to determine those who have lesions in their lungs sufficiently large to cast shadows that can be seen with the naked eye and which might be due to tuberculosis. The two screens used to select persons who need examinations, namely the tuberculin test and the x-ray film, are simple and easily conducted phases of the examination, but the determination of etiology of the lesions which cast shadows is often attended with considerable difficulty. However, the physicians of Meeker County are fully capable of solving the most difficult diagnostic problems in their own offices and hospital.

This program actually began on May 1, 1941 and has proceeded in a most satisfactory manner. The physicians have worked diligently, and their enthusiasm has not waned. On May 1, 1942 5,412 persons had been tested with tuberculin, of whom 22 per cent reacted. Other phases of the examination of the reactors had led to the diagnosis of clinical pulmonary tuberculosis in 10 persons previously unsuspected of

having this disease. The contagious patients have already been taken out of their homes and isolated in institutions.

When the work is done by the local physicians and their allies, it is slower than it would be to import a large group of workers and special equipment. On the other hand, work done by the local group is far more satisfactory. The public comes to know that its local medical profession is capable of solving this problem. Moreover, the program will be perpetuated when the demonstration period is over. Thus, in Meeker County an all out campaign against tuberculosis is under way with the idea of sweeping clean, so that for the moment no patients with contagious tuberculosis will be permitted to spread the disease. It is the intention of the local physicians to retest the nonreactors to tuberculin periodically and to reexamine as often as possible those who have become reactors as well as those found to be reactors on the first test, in order that those who subsequently develop clinical tuberculosis may have their disease detected before it becomes contagious or even causes illness.

With the Meeker County demonstration well under way, the tuberculosis committee of the state medical association turned more of its attention to the remaining eighty-six Minnesota counties. The state department of health kindly provided the average mortality rate in each county for the previous five years. From this a map was prepared from which one could readily visualize the tuberculosis situation with reference to the mortality rate in each county. Immediately we saw that there exists a wide range in mortality, in fact, from 5.5 in one county to 68.2 per hundred thousand in another. The tuberculosis mortality rate for the entire state of Minnesota in 1941 was 26.6 and for the entire nation it was 44 per hundred thousand.

The members of the Tuberculosis Committee decided that some recognition should be given counties where a great deal of tuberculosis work had been done, with a satisfactory result, for two main reasons: (1) to call attention to the fine accomplishments in these counties and (2) to stimulate the physicians and their allies in other counties to intensify their tuberculosis control program. This idea was borrowed from the United States Bureau of Animal Industry, the United States Livestock Sanitary Board, the American Veterinary Medical Association, and state veterinary organizations which had cooperated and had so effectively controlled tuberculosis in cattle. As early as 1922 they had prepared county outline maps of the entire nation, showing the incidence of tuberculosis in cattle in the various counties of each state. This original map gave a basis for planning future work, since it highlighted the areas of disease concentration. This map was revised as the work progressed. Widely distributed, the map impressed the public as well as the veterinarians, for it focused attention on the situation throughout the nation. The veterinarians and their allies

considered this one of the most valuable parts of their educational program.

The United States Bureau of Animal Industry developed a standard by which counties could receive the designation of modified areas. Any county could qualify for this designation when careful testing of its cattle revealed that not more than 0.5 per cent reacted to tuberculin. The first list of counties to qualify under the modified accredited plan was reported on July 23, 1923. Indeed, on that date there were just seventeen such counties in the entire nation and they were limited to only four states.

This was the beginning of the most spectacular and practical control of tuberculosis in recorded his-

Tuberculosis mortality rate in Minnesota per hundred thousand 1936-1940 inclusive

tory. It stimulated great interest everywhere, and such factors as local pride became important in the control of tuberculosis among animals. By Oct 1, 1928 all the counties of North Carolina had been accredited and on that date this was the first state in the nation to be designated as a modified accredited area. On May 1, 1929 the state of Maine received this designation. The veterinarians' program gained momentum, and on Nov 8, 1940 the last county in the United States became a modified accredited area and thus, the entire nation, together with its territorial possessions, was so designated. This, the greatest of all tuberculosis accomplishments in the recorded history of the world, was made possible only by the tuberculin test. All other procedures combined such as symptoms, physical signs, x-ray shadows and microscopic examinations of secretions and excretions, were not enough, it was only when the veterinarians had a delicate highly specific

and accurate biologic test to screen out all animals that had living tubercle bacilli in their bodies that such an accomplishment became possible

Our committee considered standards by which counties might qualify for accreditation with reference to tuberculosis in man. The first standard to be determined was a tuberculosis mortality rate of ten or less per hundred thousand. By this standard four counties qualified. The committee members were aware of the fact that many persons who have contagious tuberculosis die of other conditions without the tuberculosis being reported on the death certificate. The mortality rate is not the best criterion of the tuberculosis situation in a county. They are of the opinion that the incidence of the first infection type of tuberculosis, as manifested by the tuberculin reaction, is the only good available index. Therefore it was decided to adopt a second standard based on the incidence of tuberculin reactors at a given age level. It was decided that, if at least 80 per cent of all the senior students of the high schools of a county were tested and not more than 15 per cent reacted, a county might qualify for accreditation provided the average mortality rate for the past five years did not exceed 10 per hundred thousand. The medical societies of the four counties which qualified from the standpoint of the mortality rate were informed concerning the tuberculin reactor standard. Within two weeks of the date of receipt of this information, the physicians of Lincoln County, which had the lowest mortality rate, had tested practically all of the senior students in their high schools and reported that only 7.4 per cent reacted. Thus the first county in the state had qualified for accreditation.

It was then necessary to determine who should be responsible for the accreditation. The plan was submitted to the council of the state medical association, by which it was unanimously approved. It was then presented to the members of the Minnesota Department of Health with the same action. Governor Stassen was consulted and he agreed whole heartedly that the plan was good and expressed his willingness to sign the certificate of accreditation. A certificate form was prepared showing that the accreditation was granted by the state medical association, the state department of health, signed by the president of the state association, the executive secretary of the department of health and Governor Stassen. On Dec. 11, 1941 the accreditation ceremonies were held in Tyler, when the main address was given by Dr. W. H. Feldman of the Mayo Clinic, and the certificate was presented to Lincoln County by Dr. B. J. Branton, president of the state medical association.

The physicians of Olmsted County promptly tested the senior students in their high schools and found that only 8 per cent reacted. This, together with an average mortality rate over the past five years of 8.7, qualified this county and the accreditation ceremonies were held in Rochester, Minn., on May 22, 1942, when Dr. C. A. Stewart, director of the department of pediatrics of the Louisiana State University, presented the main address. This meeting was attended by many prominent persons, and Dr. H. Z. Giffin of the Mayo Clinic and president of the Minnesota State Medical Association presented the certificate to Olmsted County.

In Murray County, where the average tuberculosis mortality rate for the past five years was 9.4 per hun-

dred thousand the physicians tested the senior students in the high schools and found that only 5.5 per cent reacted. Accreditation ceremonies were held at Slayton, Minn., Aug. 28, 1942, when Governor Stassen presented a splendid address and Senator Webber participated in the program. Dr. Stephen H. Baxter, president-elect of the Minnesota State Medical Association, presented the certificate to Murray County.

In Stevens County, where the average mortality rate for the past five years was 9.2 per hundred thousand, the medical society found that only 7 per cent of the senior high school students reacted to tuberculin. The accreditation ceremonies are now being arranged.

It is often stated that the majority of senior high school students will not submit to the tuberculin test. Our experience to date has proved this statement to be erroneous. In fact, we have found the high school students eager to have the test administered. In no county to date has less than 90 per cent of these students accepted the test, and most of the remainder did not have it for such reasons as absence from school when the test was being administered. We believe that this success is due largely to informing the students and the community adequately concerning the value and practical significance of the test.

In most parts of the country the age at which persons die from tuberculosis is rapidly increasing and in some places it is well beyond middle life. Probably many of these older persons who die from tuberculosis have had the disease in chronic form for a long time, in fact, before the present campaign against the disease was really in effect. Therefore we should not allow mortality to discredit the fine work that has been done in recent years to protect children and young adults against tuberculosis and which seems to have been so successful, from the standpoint both of morbidity and of mortality, in the second and third decades of life.

In several sanatoriums and in a good many homes in Minnesota there are old persons with chronic tuberculosis who will die in the next few years, and their deaths will tend to keep the mortality rate high in some of our counties. Therefore it seems more fair to the tuberculosis workers of the state and at the same time it would reflect the excellent work done in the past decade or so if we discontinued the mortality standard and used tuberculous infection standards entirely.

The committee is considering a standard based on incidence of infection of children in the first grade, and another on incidence of infection among high school students. We believe that this will be more encouraging to our tuberculosis workers and will stimulate greater interest among them and among the public at large. With such accreditation standards every community should have a reason for striving to see that children are protected from contact with contagious persons, including those beyond middle life, and will attempt to seek out these persons and insist that they be institutionalized.

Those persons in Minnesota who are in the best position to know about the tuberculosis situation have informed us that the accreditation of counties, with reference to tuberculosis in man, has done more to stimulate interest and action than any other movement in the entire tuberculosis history of the state.

EPIDEMIC PLEURODYNIA IN BROOKLYN
IN THE SUMMER OF 1942TASKER HOWARD, MD
CHARLES A WEYMULLER, MD
JOHN EDSON, MD
ELIZABETH FITNER, MD
JANET WATSON, MD
AND
MARY L CASSIDY, MD
BROOKLYN

In 1872 Daae¹ in Norway described an epidemic characterized by the sudden occurrence of violent pain in the lower part of the thorax without concomitant signs in the chest. The pain tended to spread to the abdomen on the same side and sometimes involved the back and limbs. With this there was fever. The attack lasted but a day or so, with a tendency to recurrence once or twice within a few days. Daae spoke of the disease as epidemic muscular rheumatism. Two years later Finsen reported having observed epidemics of this character in Iceland in 1856 and 1863 and was the first to speak of this disease as epidemic pleurodynia. But little further was heard of the disease in Europe until 1930, when Sylvest's paper about a similar epidemic in Bornholm aroused so much interest that the disease was made reportable in Denmark, and 10,000 cases were reported in the next two years. Since then many epidemics have been described in Scandinavia and in the British Isles. Meanwhile, in the United States the disease was repeatedly reported, beginning with Dabney's² account of an epidemic in Virginia. It was one of Dabney's patients who dubbed the disease "the Devil's grip."

In 1935 Harder³ tabulated the American reports of epidemics which he considered to be this disease. These included the reports of Dabney (Virginia) 1888, Reilly (New York) 1899 and 1921, Payne and Armstrong (Virginia) 1923, Hangar, McCoy and Frantz (New York) 1923, Greene (New York) 1923, Torrey (Pennsylvania) 1924, Churchill, Landis and Glusker (Massachusetts) 1926, Richter and Levine (Massachusetts) 1933, Crone and Chapman (Massachusetts) 1933, Callaway (North Carolina) 1934 and Harder (Ohio) 1935.

Reports of other epidemics include Kirkwood and Stoll⁴ (Illinois) 1934, Locke and Farnsworth⁵ (Massachusetts) 1935, Hawkins and Harms⁶ (Missouri) 1936 and Fulghum⁷ (Georgia) 1940.

From the various accounts of these epidemics it is apparent that the diagnosis rests on the epidemic occurrence of the disease, that it affects children and young adults, that it occurs, in this country at least, only in the summer months, and that its clinical manifestations are fairly distinctive. The laboratory is of no positive help.

Perhaps the first description of the disease is still the best. In 1872 Daae¹ wrote

As a rule the patient has a stitch in one side of the chest, most often without any precursory ailment, but sometimes after an attack of chills, the stitch is often accompanied by pains in the back, shoulders, epigastrium and abdomen, and these pains are described sometimes as oppressive or sticking, sometimes as shooting or aching, less frequently these pains are felt also in the back, neck, legs, arms and even out in the fingers. There is considerable difficulty in moving the affected parts, especially the chest, therefore the respiration is laborious sometimes to such an extent that the patient feels as if he were to be strangled. Usually the general condition is greatly affected. There is as a rule some headache, anorexia and thirst, the bowels usually are sluggish. The tongue is generally coated. The pulse is normal or a little frequent. There is seldom any cough, so cough does not appear to go with this disease. Physical examination of the chest reveals no abnormality.

There is a great difference in the severity of the attack in the various patients. Some have a fairly mild attack and have to rest only a very short time, in others the attack is so violent that one might expect them to die at any minute. In a few of the most severe cases the patients are thus confined to bed continuously for up to fourteen days.

As a rule the patients have got up and walked about just as soon as they have been able to do it. A good many of them have then had a relapse, sometimes repeatedly. No case has terminated fatally. Many of the patients are exhausted after the disease, emaciated and feeble, sometimes they feel a stitch or stabbing pain now and then for several weeks after they have been able to begin to work.

Cases of this disease began to appear in the Red Hook section of Brooklyn in July 1942. To date at the Long Island College Hospital we have observed 166 cases. Of these, 40 were admitted to the hospital. This epidemic tends to differ in some respects from others that have been reported. There is a much higher percentage of cases showing involvement of the central nervous system, frank encephalitis having been encountered a number of times, and many of the infants had convulsions. Encephalitis was noted once in one epidemic in Sweden⁸ and was mentioned by Sylvest as having been reported by "a Danish physician" in another epidemic. MacDonald and his associates⁹ noted that an epidemic of benign lymphocytic meningitis was occurring concomitantly with the epidemic myalgia in Cincinnati in 1935. These authors speculated on the relationship between these two groups of cases.

Many authors have commented on the absence of infection of the upper respiratory tract in these patients, but all of the infants in our series and about three fourths of the older patients showed some congestion of the pharynx. This is not altogether exceptional, however, since more than half of the cases reported by Attlee and his associates¹⁰ in England in 1924 and all of Fulghum's⁷ in the 1940 Georgia epidemic were said to present pharyngitis.

We have noticed some differences in the manifestations of this disease in adults and children in this epidemic. It seems wise to consider the two groups separately.¹¹

From the Departments of Medicine and Pediatrics of the Long Island College of Medicine and the Long Island College Hospital.

11 Specimens of nasal washings, stools, spinal fluid and blood from many of these patients have been submitted to Dr Karl Habel and Dr Michael L. Furcolow of the National Health Institute, Bethesda, Md for investigation as to the etiologic factor of this disease.

ADULT CASES

Abstracts of a few cases will illustrate the typical course in adults

CASE 1—D McL, a girl aged 13, admitted July 1, 1942, suddenly had chilliness, fever and pain in the right upper quadrant four days before. The pain would follow coughing, laughing or raising the right shoulder. She had daily short recurrences of pain and fever. On the night of admission the pain was much more intense.

The temperature was 101.6 F, the pulse rate 100 and the respiratory rate 20. The pharynx was clear. There were a slight respiratory lag and moderate costovertebral tenderness on the right side and slight spasm and tenderness in the right

Laboratory examination revealed 7,800 white blood cells with 71 per cent polymorphonuclear leukocytes, the urine was normal. Culture of material from the throat showed gamma streptococci predominating and a few beta streptococci.

The next day she felt entirely well and was discharged after three days. Four days later she was readmitted to the hospital stating that for two days she had suffered from head ache, weakness, irritability, general aching pains, vertigo and sensitivity to noise. She had fainted immediately before admission.

The temperature was 101.1 F, pulse rate 88, respiratory rate 22 and blood pressure 102 systolic and 64 diastolic. She was lethargic, apathetic and acutely ill. There was photophobia. Her pharynx was slightly injected. There was pain in the

upper quadrant. Roentgen examination was thought to show a slight congestion in the right lung.

Laboratory examination revealed 5,200 white blood cells with 81 per cent polymorphonuclear leukocytes.

The temperature became normal and pain was relieved in sixteen hours. There was no further recurrence. Convalescence was rapid.

CASE 2—J O, a woman aged 22, admitted Aug 3, 1942, three days before admission began to suffer from pain in the right side of the lower part of the chest on respiration and to a lesser degree on the left side. She had chills and fever and aching of her back and legs. Her throat was dry and she was weak and dizzy.

The temperature was 99.8 F, the pulse rate 82, the respiratory rate 15 and the blood pressure 102 systolic and 60 diastolic.

She was profoundly prostrated and apathetic. Her pharynx and tonsils were moderately inflamed. Neurologic examination was negative.

occiput on extreme flexion of the neck. Abdominal reflexes were absent. The Brink's reflex was elicited on both sides.

Laboratory examination revealed 5,950 white blood cells with 54 per cent polymorphonuclear leukocytes. The sedimentation rate was 65 mm in one hour. The urine was normal. The spinal fluid, August 10 (tenth day of the disease), showed pressure of 240 mm of water, 261 cells with 97 per cent lymphocytes, a test for globulin was negative, the protein was 40 mg, sugar 62 mg and chlorides 679 mg per hundred cubic centimeters. August 15, spinal fluid showed a pressure of 60 mm of water and 41 cells, all lymphocytes, a test of the globulin was negative. August 26 it showed a pressure of 70 mm of water and 7 cells, all lymphocytes.

Her temperature was normal except for one slight rise on the fifth day. After two days she was normally alert and her photophobia and general discomfort had disappeared. Her convalescence was normal except for a recurrence of headache when she tried to sit up.

The child of a neighbor who lived in the same house as this patient was admitted to the Long Island College Hospital because of similar manifestations. J O had held the child in her arms during the interval that she was at home. An abstract of this child's illness is reported in the section on children (case 7, R B, aged 5 years).

CASE 3—T S, a girl aged 14 years, admitted Aug 8, 1942, two hours before admission, while at the movies, had a sudden intermittent stabbing pain in the right upper quadrant which was aggravated by respiration. She had a chill and fever.

The temperature was 103.2 F, pulse rate 120, respiratory rate 30 and blood pressure 104 systolic and 70 diastolic. The pharynx was slightly injected. There was a slight lag on the right side of the chest with diminished breath sounds and

He had headache and profuse perspiration. His temperature was 104 F. The next morning he was symptom free. Thirty-six hours later there was recurrence of pain in the left side of the lower part of the chest, fever, headache and sweating. This bout lasted thirty-six hours and was followed by sixteen hours of freedom from symptoms. All these symptoms recurred a third time some twelve hours before admission to the hospital.

The temperature was 102 F, the pulse rate 76, the respiratory rate 24 and the blood pressure 118 systolic and 78 diastolic. His pharynx was slightly inflamed. There was a slight lag in the left side of his chest and moderate tenderness of the left upper quadrant. Roentgen examination of the chest was negative.

Laboratory examination revealed 5 000 white blood cells with 41 per cent polymorphonuclear leukocytes. The sedimentation rate was 43 mm in one hour.

slight tenderness in the right upper quadrant with some cutaneous hyperesthesia. Roentgen examination of the chest was negative.

Laboratory examination revealed 9,600 white blood cells with 73 per cent polymorphonuclear leukocytes. The urine was normal. The spinal fluid showed a pressure of 170 mm of water, no cells and a trace of globulin. The sedimentation rate was 91 mm in one hour.

The pain persisted for about eight hours. Her temperature was normal on August 11 but rose to 102.6 F the following day with the appearance of pain in both sides of the chest. On August 12 the temperature was normal and the patient was comfortable. On August 13 the temperature was 103.6 F and there was more pain in the neck, abdomen and lower part of the chest (corresponding to the pattern of diaphragmatic pain, as is true in so many of these cases). On August 14 the temperature was normal and a rapid convalescence followed.

CASE 4—P I, a youth aged 15 admitted Aug 26, 1942 five days before was suddenly attacked with severe pain in the right lower quadrant which was aggravated by respiration.

The symptoms and fever subsided on the second day. On the third day he had one further paroxysm of fever and at this time there was pain in the right side of the chest with a pleural friction rub. The pain and fever subsided in sixteen hours but the friction rub persisted for three days.

The boy's father suffered a similar attack with but one bout of symptoms nine days before the patient was taken sick. A brother aged 11 years had a single attack two days before.

PEDIATRIC CASES

CASE 5—A T, a boy aged 7 years, three days before admission to the Long Island College Hospital had severe pain high in the right side of the abdomen but no fever. After twenty-four hours he still had this pain, vomited and was moderately incapacitated. On the day of admission he had more severe abdominal pain, vomited and had a temperature of 104 F. He was decidedly prostrated and feverish and had labored grunting respirations and a definitely reddened pharynx. His abdomen was tender and splinted.

Laboratory examination revealed 10,850 white blood cells with 80 per cent polymorphonuclear leukocytes. The sedimentation rate was 18 mm in sixty minutes. The urine was normal. Culture of material taken from the throat yielded mixed pneumococci and hemolytic streptococci. Roentgen examination of the chest was negative.

He improved greatly in all respects after twenty-four hours—his temperature became normal and the pain in the abdomen and lower part of the chest disappeared. The pharynx paled and his convalescence was rapid and complete.

Seven other children aged from 2½ to 11 years were admitted because of an almost identical syndrome (table 2). There were 96 additional children seen in the accident room and in the outpatient department who were similarly affected but were cared for at home.

CASE 6—G M, a boy aged 12 months, admitted to Long Island College Hospital July 17, 1942, two days before had severe abdominal pain of intermittent character. He became progressively more ill with high fever, and a generalized convulsion of short duration developed while still at home.

On admission he was still twitching and had a temperature of 105 F, pulse rate 134 and respiratory rate 28. His pharynx was red and edematous and there was a purulent postnasal discharge. His abdomen was normal. His neck was not rigid.

Laboratory examination revealed 6,400 white blood cells with 44 per cent polymorphonuclear leukocytes. The urine was normal. Spinal fluid was clear, pressure was moderate and there were 73 cells. Culture of material taken from the throat yielded a large number of pneumococci.

There was a decided clinical improvement after twenty-four hours. There were no further convulsions. The temperature ranged between 99.9 F and 100.6 F during the second twenty-four hours, then it became normal. The abdominal pain disappeared and pharyngeal injection quickly subsided.

CASE 7—R B, a boy aged 5 years, became ill one day before admission with headache, chills and fever. His fever rose, severe pain in the back and neck developed and he was admitted to the hospital Aug. 8, 1942 with a temperature of 104 F. He was prostrated and decidedly drowsy, and there was twitching of his hands and feet. His neck was definitely rigid and there was extreme stiffness of his back. He did not have a convulsion. His throat was very red. His abdomen was tender particularly in the right upper quadrant and over the liver, which was felt one and one-half fingerbreadths below the costal margin.

Laboratory examination revealed 18,500 white blood cells with 77 per cent polymorphonuclear leukocytes. Culture of material taken from the throat yielded large numbers of hemolytic streptococci. The spinal fluid on admission showed moderately increased pressure, 840 cells with 67 per cent lymphocytes, a test for globulin was positive and sugar was 48 mg per hundred cubic centimeters. Two days later it showed 60 cells, all lymphocytes, the protein content was 45.6 mg. On the fifth day in the hospital it showed no cells, protein was 23 mg and sugar 81 mg. Cultures of all specimens of spinal fluid were negative.

After twenty-four hours his temperature was normal and remained so. His neck and back were stiff and troublesome for two to three days. The abdominal pain lasted three days but he was symptom free after seventy-two hours. No weaknesses or other abnormal symptoms remained.

This child had been in direct contact with adult J O (case 2), who had meningoencephalitic symptoms. This boy's obvious meningoencephalitic manifestations cleared up with extraordinary rapidity and without sequelae to date. The clinical course, the presence of the epidemic and the contact with adult J O appear to justify inclusion of case 7 in this report.

COMMENT

The prominent symptoms in adults were fever and severe pain in the upper part of the abdomen or lower part of the chest or both sufficient to make respiration painful and difficult. The abdominal symptoms were frequently so severe that surgical consultation was

sought. The recoveries were prompt, often within twenty-four to forty-eight hours, though recurrent paroxysms of pain and fever were frequent. Frank pleurisy was encountered three times. The Scandinavian writers consider this a rare complication, but in England it was not uncommon, and in one Massachusetts series reported by Locke and Farnsworth the incidence was 14 per cent.

Meningoencephalitis occurred in 5 of our adult patients. This was characterized by headache, apathy, vertigo and photophobia. There was mild nuchal rigidity in a few cases and a positive Babinski sign in 1 case. The spinal fluid usually showed a frank pleocytosis mostly lymphocytes. The patients all recovered promptly and no sequelae were noted. It is interesting to compare this finding with the high incidence of convulsions observed in the infants seen in this epidemic. Of the 18 children hospitalized with this presumptive diagnosis, 8 were under 2 years (the youngest 6 months) and all had generalized convulsions. None of the children of the 10 who ranged from 2 to 11 years had convulsions.

The pediatric cases depicted in table 2 had in common severe abdominal or chest pain or both, high fever usually of one to two days' duration, labored respirations, moderate vomiting but no diarrhea, severe pharyngitis and quick and complete recovery. Of the 8 under 2 years, all had generalized convulsions of alarming severity. R B (aged 5 years) alone of 11 older children had meningoencephalitic manifestations which included drowsiness, twitching, rigid neck and stiff back. He did not have a generalized convulsion.

The leukocyte counts were widely variable and the spinal fluid examinations were normal except that G M (aged 12 months) had 73 cells and R B had 840 cells when admitted.

Early in July 1942 the first cases among children were believed to be the usual so-called epidemic gastro-duodenitis or severe pharyngitis with abdominal pain so vividly described by Brannemann and so common in pediatric practice. However, the case incidence was about 10 a day, at first all from the Red Hook Housing Project and then roughly fanning out from there. The abdominal pain was extraordinarily severe and constant, violent generalized convulsions were seen or reported in most of the infants and in many of the older children who came to the outpatient department or the accident room. This alarming syndrome quickly and completely cleared. There were numerous adult cases at this time with a symptom complex recognizable as epidemic pleurodynia. Only 1 child admitted to our hospital had definite pleuritic involvement, although one of us (C A W) saw an 11 year old girl with obvious pleuritic involvement accompanying the typical epidemic pleurodynia syndrome. So far there have been no recognizable sequelae.

These cases are being reported at the present time, even though the epidemic is still active, for the purpose of calling it to the attention of other observers in the East who may encounter this disease.¹²

CONCLUSIONS

1. Epidemic pleurodynia appeared in Brooklyn in July and August 1942. To date 166 cases have been observed, 40 of which were admitted to the Long Island College Hospital.

¹² Since submitting this paper for publication we have encountered only 5 further cases of epidemic pleurodynia. They were in adults 2 being over 30 years of age, 1 34 and the other 35.

2 An unusually high incidence of pharyngitis has been evident in this epidemic

3 Abdominal symptoms, as has been emphasized in the course of other epidemics, were sometimes severe enough to suggest an abdominal emergency of a surgical nature

4 In this epidemic an unusually high proportion of patients exhibited evidence of meningoencephalitis. Practically all of the infants had convulsions

5 As in other epidemics of this disease the symptoms have subsided quickly

6 So far no sequelae have been observed

CYTOPLASMIC MODIFICATION OF GENETIC TRENDS

WILLIAM F. PETERSEN, M.D.

AND

ALVIN MAYNE, M.B.A.

CHICAGO

Does the condition of the mother influence the developing embryo? This question is one that comes up every so often and we are apt to dismiss it without much thought because we accept the textbook dictum that the development of the human embryo is strictly gene determined. But geneticists today are by no means as dogmatic as they were a decade ago. The vast bulk of the cytoplasm of the egg and its possible significance in modifying genetic trends is receiving more and more attention, and Porter's¹ experiments lend support to this idea.

The observations that we shall present are concerned wholly with the problem in the human being and are therefore based on statistical analysis on the one hand and on the demonstration that environmental impacts (weather as an example) can profoundly modify the bodily chemistry from day to day.² Modification of the condition of the maternal body fluids and tissues in which the early development of the embryo takes place leads to the realization of the importance therein implied in modifying genetic trends during the early and very critical stages of development.

The very simplest demonstration of the effect of season is evident in Li's³ studies of the weight of newborn infants when examined on the basis of the month of conception. At a time when the maternal organism is relatively catabolic the infants conceived are light in weight, in the autumn, when anabolism is accentuated, infants conceived are relatively heavier (fig. 1).

If season, in other words, the cumulative effect of certain environmental situations (chiefly weather and light but integrated with diet and physical activity) can be causative in the fashion here indicated, we must be interested in related possibilities in two diverse directions: (1) the possible effects of long-range trends

in the meteorological environment that may be classified as climatic cycles—related in a rather definite way to periods of solar turbulence (sun spot cycles), (2) the possible reflection of shorter trends, namely the effect of individual weather episodes at about the time of conception. This involves the organic reaction to the constantly pendulating cyclonic atmospheric circulation with its brusque atmospheric fronts, the so-called 'cold waves' or 'heat waves' with which we who live in the northern hemisphere are all familiar.

Will all the fluctuating chemical tides that are thereby initiated bring about changes in the developmental trend of embryos? The investigation of the possible effects on the human being have been extended in several directions and of these we briefly present the following.

The Habitus of the Newborn—That is the weight/length ratio which in turn may reflect either an anabolic or a catabolic trend established in the embryo.

The Weight/Length Ratio of the Adult—On the assumption that a trend once established in the embryo as observed in the newborn may persist to adult life.

Malformations—Geneticists accept the possibility that malformations may be induced by genetic or environmental factors. Our observations are therefore directed to the possibility that metabolic factors, initiated by the environmental forces that we have mentioned, may be concerned in the production of such variants.

Sex Ratio—Maleness being associated with an increased trend to catabolism (approximately 10 per cent increase in the consumption of oxygen), we have investigated the possibility that the condition of the ovum or the maternal metabolic status might condition the genetic balance and thus exert an influence on the sex ratio.

Disease Susceptibility—With resistance to disease, longevity, and so on, in part conditioned by habitus and by metabolic trends, the investigation was extended to the possibility that early conditioning of the embryo might find adult reflection in increased or decreased resistance to disease as finally determined by death certification.

Before proceeding it may be useful to examine these developmental possibilities in the form of a simple diagram (fig. 2). Assuming that the metabolic gradient of the milieu (we can think in terms of oxygen adequacy or inadequacy, pH levels, potassium/calcium ratio, temperature hydration or any other organic balance that we may choose because they are all interrelated) pendulates between two poles the normal genetic trends proceed on a gene determined basis if the swing in either direction is within moderate limits.

If the amplitude of the biochemical swing becomes greater, then gene determined potential may be modified with a greater tendency to (1) maleness (2) slenderness, (3) predisposition to characteristic disease potential (schizophrenic, tuberculous), (4) malformation (due to lessened cell cohesion) when the trend is toward greater catabolism, lower pH and an increase in permeability and so on or to (1) femaleness (2) broadness (3) manic-depressive psychosis (4) mal-

Fig. 1—Weight of newborn infants by month of conception 31,000 in the group (From Li³).

In the complete reprint of this paper a discussion of the statistical techniques employed has been provided.

formation (due to increased cell cohesion or delay in separation) when the pendulum swings too far to the anabolic side at certain critical periods in development

HABITUS

Starting out on the basis of the observation that the weight of the newborn infant varies with the season of conception, we studied the weight/length ratio of newborn infants and made an examination of over 45,000 obstetric records from six Chicago hospitals, extending over a period of thirteen years. This study revealed striking long-range trends in body proportion of the newborn. The average weight/length³ ratio of the newborn in each week was computed according to sex. The correlation between a series of ratios for male offspring and a series of ratios for female offspring was high (0.83), indicating that a factor common to all was operative to bring the week-to-week weight/length ratio of the two sexes in harmony.

The curves reveal that broader habitus reached a crest for infants born in 1928-1929, this was followed by a rapid shift toward slenderness in 1930, then followed a reversal of trends to broadness for the years 1933 to 1938, followed by a renewed decline in 1939.⁴

The Variability of Habitus—When variability of the weight/length³ ratio was computed by quartile deviation, it was noted that infants conceived in 1928 showed greater variability, then followed greater uniformity for the years 1931-1933 giving way in turn to a second crest of greater variability in 1937-1938.⁵

Thus it would appear that long-range trends in the habitus of the newborn do exist and that for the material presented the cycle was approximately ten years. The crests in variability corresponded to periods of greater sun spot activity.

THE RELATION TO THE WEATHER AT THE TIME OF CONCEPTION

Further analysis of the material with respect to possible causal relationships with barometric pressure⁶ reveals striking consistency. It was found that the temperature and barometric pressure of a week or two after the possible conception was most closely related to the habitus of the newborn. The nature of the association between temperature and body stature was consistent from season to season. Regardless of season it was found that the heavier and shorter offspring were

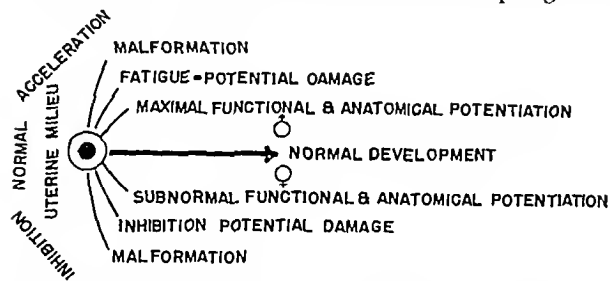

Fig. 2—Possible modification of genetic trends by diverging trends in milieu with resulting modification of sex habitus, disease predisposition and anatomic defects.

associated more frequently with presumptive conception at higher temperatures.

MALFORMATIONS

A study of the temperature and barometric pressure movement at the probable period of conception of 1,114

cephalic malformations covering a twelve year period (individual records from death certificates of the Chicago Health Department) indicates that they were conceived under conditions dissimilar to those for normal conceptions. By means of statistical tests it is indicated that the frequency of malformed births under certain

Fig. 3—Lower curve, sex ratio of the newborn Chicago births September-October-November and December 1934. Dotted line, daily ratio. Solid line, five-day moving average. Daily maximal and minimal environmental temperatures at conception superimposed.

temperatures and barometric pressures is sufficiently different from the frequency of normal births under similar conditions to warrant the conclusion that differences cannot be entirely attributable to chance.

SEX RATIO

When one graphs the day-by-day sex ratio of the newborn for a city population (we have made use of Chicago, Detroit and New York records) a most striking pendulation of the sex ratio (fig. 3) becomes evident and when related to the environmental temperature of the presumptive time of conception (280 days before birth) it would appear that the trend to maleness is in some fashion related to periods of increasing cold and the trend to femaleness with periods of greater warmth.

Statistical tests indicate that in three of the four seasons—winter, spring and summer—the temperature deviation from normal and the sex ratio of births 285 days later are associated to an extent which cannot be entirely attributable to chance. In the winter months of conception we may expect that extreme cold or heat on the 285th day prior to birth will be associated with an increase in maleness. During the summer months the same pattern is observable with a tendency for greater temperatures to be associated more strikingly with the increase in maleness. In the spring months, however, the association is not clear. There appears to be a tendency for increased femaleness to be associated with extreme temperatures.

COMMENT

We have here presented evidence that environmental variability (weather, season, climatic cycles) reflected¹ in corresponding human biochemical and biophysical waves may be a factor in modifying genetically governed developmental trends. Such interference is presumably of significance in conditioning the cytoplasm of the ovum before fertilization or during certain early and critical stages of organic development.

The meteorobiologic integrations here touched on have been studied as part of a broad survey of human reaction to weather. The direct effects in the normal

12 Both the passage of a polar front as well as high temperature crests can be associated with a transient relative alkalosis and with this a relative anoxia. In turn this will be followed by a relative acidosis.

17 In the organism such periodic impacts set up a series of corresponding biochemical waves which in turn may be negated or amplified by succeeding environmental impacts of like or diverse origin. Under sensitivity or reactivity of the individual organism either because of habitus inadequacy or other reasons will naturally modify the rhythm.

4 The graph figure 12 is included in the statistical study.

5 The graph figure 13 is included in the statistical study.

6 The barometric pressure was used here purely as an index with the definite reservation that it does not give a comprehensive picture of change in air mass.

and sick individual are as obvious today as they were to the hippocratic physician but, as happens not infrequently, the commonplace is apt to be ignored. The more subtle effects such as those that may involve conditioning of genetic trends here under discussion while not of immediate medical or pathologic interest, should be considered from the point of view of organic selection of adaptation and of human evolution.

Actually our observations merely confirm the earliest recorded statement on heredity, namely "wherefore it is natural to realize that generation, too, varies in the coagulation of the seed and is not the same for the same seed in summer as in winter nor in rain as in drought" (Hippocrates: Airs, Waters, Places)

ABSTRACT OF DISCUSSION

DR ALVIN MAYNE, Chicago. The variations from day to day in sex ratios in the weight-length ratios and in the frequency of malformations cannot be attributed merely to chance but there exist factors that do influence the variations significantly. In many of these studies we have used a large population. For example, in our studies on sex ratio we have studied the births of over thirty thousand offsprings. In our study on weight-length ratio we used over 45,000 observations and in our study of malformations we compared a thousand malformations to a normal population of births of over thirty thousand. Hence, while the relationships to certain factors of environment may be slight because of the large numbers we have shown that they could not have been due to chance. There must be some factors common to the entire population, and one might have been the diet of the population. However, we have no records of the diet of the mothers at the time of conception, and we can almost rule out racial and heritage factors because these data are from the city of Chicago with a diverse racial population. The environmental conditions are common to nearly all of the population, that is, in general the mothers have been exposed to the variations in temperature and barometric pressure and air masses that pass over the city of Chicago. We have records on the weather in Chicago that we can date back to the probable time of conception. We have made use of this material principally because we feel that that is one of the common factors involved. I have broken up the sex ratio of 33,000 babies into four groups whether they were conceived in winter, spring, summer or autumn. We have fairly good evidence that about two hundred and eighty-five days before birth the temperature does have some effect on the sex ratio of the offspring. We can draw conclusions because the probability that such relationships as we have found exist merely through chance is small, and in each case in winter, spring and summer the probability is less than one out of a thousand, by using the latest statistical methods.

Control of Body Weight—We have seen that surplus calories of ingested food, whether taken in the form of protein, fat or carbohydrate, tend to accumulate in the form of body fat. And overfatness always means that the intake of food calories has been out of proportion to the expenditure of energy by the person concerned. There is more tendency to overweight in some people than in others, and undoubtedly this sometimes extends beyond the question of appetite to endocrine and perhaps other constitutional differences, yet the fact remains that for the individual the control of body weight is essentially a matter of a proper balance between what is ingested as food and what is oxidized in the energy metabolism. If one tends to become too fat, the remedy is to eat less or to burn more.—Sherman, Henry C. *Chemistry of Food and Nutrition* New York, Macmillan Company, 1941

Clinical Notes, Suggestions and New Instruments

TANTALUM AS A METALLIC IMPLANT TO REPAIR CRANIAL DEFECTS

A PRELIMINARY REPORT

LIEUTENANT COMMANDER O HUGH FULCHER MC V (S) U S N R

Cranial defect in military surgery represents a most important problem because of the frequency of occurrence and because it renders a man unfit for military duty unless it can be adequately repaired. Therefore an adequate method of repair is urgent—one which can be performed by the general surgeon as well as by the neurologic surgeon in any ordinary general hospital wherever it may be located. Moreover, the repair should render protection to the intracranial structures against blows, changing atmospheric pressures and changing bodily positions which should approximate that afforded by the normal

Fig. 1—The cranial defect destroys the left boss of the forehead

Fig. 2—Cosmetically the defect involves a part of the face

cranium. The convalescence following the operative procedure should be brief to keep 'as many men at as many guns as many days as possible'.

REPORT OF CASE

R A P, aged 23 a fireman, second class attached to submarine duty, had received a compound depressed fracture of the left frontal region on May 5 1941 when struck by a closing compartment door of a submerged submarine. On regaining consciousness a few minutes later he found himself in the sick bay with his head bandaged. Two days later some cranial fragments were removed at a naval base hospital. Subsequently he was transferred to another naval base hospital where a second operation was performed which consisted of removing bony fragments. He was transferred to U S Naval Hospital, Washington D C, on October 15 for further treatment.

On admission the complaint consisted of annoying pulsation in the area of the cranial defect recurring attacks of frontal headaches, vertigo and a sensation of impending syncope on change of position. He was annoyed by the bulging of the area over the cranial defect on bending over and a concavity

Read before the Washington Academy of Surgeons April 10 1942.
The tantalum used in this case was furnished by Finsteel Metallurgical Corporation North Chicago Ill.

of this area on standing. He feared crowds because of the curiosity and questions evoked by his appearance. He was mentally depressed because he had been advised that the cranio cerebral injury had rendered him unfit for further active military duty. He had lost 20 pounds (9 Kg) since the accident.

Fig 3—The cranial defect measures 3 by 4 cm. There are some depressed bony fragments along the anterior margin.

Fig 4—The tantalum plate has been reduced to correct size by tin snippers, hammered into desired contour and fitted to mold. It is prepared for insertion.

Examination revealed that he was moderately well nourished with a conspicuous cranial defect involving the left frontal boss which measured about 4 cm in diameter (figs 1 and 2). The overlying soft tissue was depressed and pulsating and had

two vertical scars. When the patient strained or bent forward the overlying tissue would bulge, and the patient complained of vertigo, tinnitus and a sensation of fainting. In the prone position the overlying skin would also bulge. The temperature, pulse and blood pressure were within normal limits. The remainder of the physical and neurologic examinations revealed only normal conditions.

Röntgen studies of the cranium revealed a large rounded defect about 3 by 4 cm in the left frontal region several centimeters above the orbit. The anterior edge showed a shelving margin which projected inward about 2 cm and which represented depressed fragments of bone (fig 3).

Another surgical procedure was deemed necessary to remove the remaining depressed fragments of bone and to repair the cranial defect. Furthermore, the cranial defect involved the face, and the patient was anxious to have the facial symmetry restored.

Capt F R Hook of the Medical Corps suggested the use of a tantalum plate to repair the cranial defect. He had used tantalum plates in orthopedic procedures and had demonstrated by reoperating eight months after the insertion of the plate that bone during regeneration would incorporate the metal and that soft tissues would adhere to it. Mr I R McCall,

Fig 5—Tantalum plates snugly placed in situ covering the cranial defect five days after operation.

A metallurgist determined by experiment that the plate should be 25 mils thick to render adequate protection. Dr C C DeFord of the dental corps prepared a mold of the cranial defect. The plate was then cut approximately to the correct size by means of tin shears and hammered to the desired contour, which could be determined by the mold and by adjusting the plate over the right frontal boss of the patient. Following this the plate was further trimmed to the perfect size. Three perforations were made to permit the escape superficially of any serum that might collect beneath the plate in situ (fig 4). It was sterilized by boiling.

On November 24 the cranial defect was explored under local anesthesia by excising the lateral vertical scar present. The dura appeared intact but there were two depressed fragments of bone along the medial border of the cranial defect which were removed. The pericranium about the border of the cranial defect was elevated, the prepared tantalum plate laid in place and its size marked by means of a sharp knife. The plate was then removed and a bed prepared by the use of a chisel and a motor driven emery wheel. The depth of this bed was equal to the thickness of the tantalum inlay so that there would be no elevation or depression at the junction of the bone and metal. The plate was then dropped in place, the available pericranium placed over its border and the skin closed with fine dermal sutures (fig 5). The patient remained in bed only two days, and the convalescence was uneventful.

On November 29 the sutures were removed and about 4 cc of bloody fluid was aspirated. On December 10 he was granted a leave for four weeks to visit his home, during which time his activities were not restricted and he was entirely free of all symptoms. The cosmetic result was satisfactory (figs 6 and 7) and the plate offered ample protection to the intracranial structures.

The patient returned from his sick leave on Jan 8, 1942, anxious to return to active duty. He was mentally alert, liked social life and was completely adjusted. On January 13 and 14 a thorough examination was made to determine his qualification for submarine duty, which included his ability to withstand an air pressure of 50 pounds to the square inch. He passed this test satisfactorily and on January 16 was returned to submarine duty on a North Atlantic patrol.

COMMENTS

This patient was completely rehabilitated within two months of the operation for repair of the cranial defect. Thus a highly trained submarine fireman who could not have been replaced immediately was returned on active duty. Moreover, he had been rehabilitated socially to the extent that he had regained his former personality. He possessed his normal appearance, with the exception of two scarcely visible vertical scars in the region of the left side of the forehead.

It is not necessary to make a bed in the cranium to receive the plate as it was placed on the bony border about the defect in another case with equally good result. A bed for the metallic inlay was desirable in this case for cosmetic reasons. Otherwise there would have been a slight elevation about the border of the plate.

In 1939 Grant and Norcross¹ reviewed the literature on the methods used for repairing cranial defects and reported their experience with the craniopericranial graft. A study of their excellent work clearly demonstrated that there existed

no adequate method for repairing cranial defects at that time. Since then Lipscomb and Grover,² Geib,³ Peyton and Hall,⁴ and Beck⁵ have reported the use of vitallium plates with good results. However, vitallium is an alloy which must be cast and will not lend itself to hammering; it cannot be cut or bent. Since the mold for casting is made over the soft tissues and since the soft tissues do not accurately represent the cranial contour or defect, the plate rarely fits snugly and usually requires a compromise in adjustment. Furthermore, casting is frequently impracticable in some military hospitals.

Fig 6—Appearance sixteen days after operation.

Tantalum is element 73 of the periodic table. It has approximately the physical properties of cold rolled steel and the chemical properties of glass. It can be secured in plates or sheets of any size desirable, and the thickness should be

25 mills. It is inert and can be cut, bent or hammered, and of course it can be sterilized by boiling or by any recognized chemical method. It will give protection at the thickness of 25 mills, which will approximate that of the normal cranium.

Lieut (J g) R H Pudenz of the Medical Corps has demonstrated by animal studies and by biopsy of the scalp of one of my patients that soft tissues will adhere to tantalum to the extent that it has to be removed by a periosteal elevator, which corroborates the observations of Captain Hook. Thus it may be possible in many instances to repair the cranial defect by the use of a tantalum plate at the time that the bony fragments are removed immediately following injury. If this is done, sulfanilamide powder should be "dusted" into the wound and on each side of the plate. Complete hemostasis is imperative.

Fig 7—Note symmetrical contour of forehead.

Tantalum plates of 25 mill thickness for repair of cranial defects should be included in the surgical supplies of every general military hospital.

CONCLUSION

The method described of repairing a cranial defect involving a part of the face by the use of a tantalum implant has afforded protection to the intracranial structures approximating that offered by the normal cranium. The convalescence in my case was brief and the normal facial contour was restored.

RECURRENT INTRACRANIAL HEMORRHAGES IN A PATIENT WITH HEMOPHILIA

SAMUEL BAER, MD, HAROLD L. GOLDBURGH, MD,
AND BEATRICE PEARLSTINE, MD, PHILADELPHIA

Surprisingly little has been added to our knowledge of the etiology and pathogenesis of hemophilia since it was first described as a distinct clinical entity by Otto in 1803. There is still some discussion concerning the essential clinical features of the condition. Most observers, however, agree that hemophilia is a blood dyscrasia occurring almost exclusively in males and transmitted according to mendelian laws of inheritance by the female. The disease is characterized by a history of repeated hemorrhages, a prolonged clotting time and a normal bleeding time.

Trauma almost invariably precedes hemorrhagic episodes according to Eley.¹ A fracture, contusion, laceration or surgical procedure of even the most minor degree may start the bleeding. Approximately 75 per cent of the cases present orthopedic complications (hemarthroses) of some sort.²

All are agreed that hemorrhage into the central or peripheral nervous system is very unusual. In a complete review of the literature prior to 1911 Bullock and Fildes³ found only 19 cases of hemophilia in which there were neurologic complications. In 14 of these intracranial hemorrhages were noted. From 1911 to 1930 Seddons⁴ found mention of only 1 case

of damage to nerve tissue by hemophilia. Of the 29 cases of Seddon's series only 2 presented neurologic lesions and none intracranial bleeding.

It can be seen, therefore that intracranial bleeding occurring in a hemophiliac is a rather rare complication. Our patient exhibited at least two and possibly four episodes of such hemorrhage.

Fig 1—Large clots attached to under surface of dura

REPORT OF CASE

History—W R was born May 27, 1920 and until his death at the age of 22, his history was characterized by repeated hospitalizations.

When circumcision was performed ten days after birth he bled for twelve hours. Transfusions were required to help stop the bleeding.

His first admission to the Jewish Hospital was at the age of 15 months. A known hemophiliac, he was admitted for treatment of bleeding gums. Hospitalization occurred again in 1923 at the age of 3 years. The diagnosis on admission was meningismus. Continuous vomiting had been present for three days. Examination revealed nuchal rigidity, a positive Kernig sign, a positive Babinski sign and some hyperesthesia. Spinal puncture was not performed.

In 1924 he was admitted a third time for treatment of continuous bleeding resulting from a laceration of the lip. Three years later he was hospitalized for bleeding following the accidental loss of a tooth.

At the age of 13 he was again referred to the Jewish Hospital, this time for treatment of a spontaneous subarachnoid hemorrhage. It was discovered at this time that he had been treated for a similar episode at another hospital two years previously. Two spinal taps were grossly bloody, and laboratory studies revealed a moderate hypochromic anemia, a bleeding time of three and one-half minutes and coagulation time varying from nine to nineteen and one-half minutes.

His sixth and final admission occurred Sept 1, 1942 at the age of 22. He was admitted to the medical service of Dr Harold L. Goldburgh complaining of severe headache and vomiting of three days' duration. One convulsion had occurred the day prior to hospitalization. Examination revealed a heart rate of 50 and evidence of multiple joint deformities (hemarthroses). Neurologic examination revealed hyperactive deep tendon reflexes and a positive Babinski sign on the right side. Spinal fluid was grossly bloody. Laboratory studies were consistent with the diagnosis of hemophilia (bleeding time two and three-fourths minutes, clotting time thirteen and one-half minutes, normal vitamin C level and normal prothrombin time).

Evidence of increased intracranial pressure persisted. The headache became worse, the temperature rose to 104-105 F,

nuchal rigidity was severe and inequality of pupils was present. Stupor became deeper and severe opisthotonos and facial asymmetry became apparent. A cerebral cry was almost constantly present.

Treatment was wholly ineffective. Transfusions had to be discontinued because of the development of autoagglutinins. Widespread hemorrhages occurred in the skin and at various points of pressure. Death occurred on September 16, sixteen days after admission.

Autopsy—Examination three hours post mortem revealed emphysema, patchy pneumonitis at the right base and gastric and retroperitoneal hemorrhages. There was a left parieto-frontal encephalomalacia and a large subdural hematoma. A detailed neuropathologic examination was made by Dr N W Winkelman, whose report is here given.

Gross Examination The brain was small and extremely bloody. The outstanding feature was the presence of well organized clots under and attached to the dura on both sides. This was especially noticeable on the left side, where the clot reached a thickness of almost 4 cm (fig 1). This point was reached in the form of a nodule which was in the superior parietal area. It had compressed the underlying brain structure so that it was flattened. It acted in the same way as an overlying meningioma. The clot on the left side was ragged and irregular but larger than the one on the right which was much thinner and had not greatly compressed the underlying cortical tissue.

There was blood not only in the subdural space bilaterally but also in the subarachnoid space. It was not however primarily subarachnoid bleeding but apparently had broken through the arachnoid. While the entire soft meninges were blood stained they were not overfilled with blood. Only in relation to the large blood nodule was there an excess amount of blood filling the convolutional interspaces.

At the base of the brain there was an excessive amount of blood and the structures stood out clearly. The blood vessels were small, bluish and not sclerotic.

Sections through the pons, medulla and cerebellum showed no gross evidences of bleeding or any other gross lesions. There was, however, considerable congestion.

Section through the brain showed no ventricular dilatation. There was only moderate congestion. There was no intra-cerebral bleeding. The left parietal lobe beneath the large blood clot was seen to be compressed and distorted (fig 2). The tissue beneath was necrotic but not hemorrhagic. This area of necrosis occupied the posterior part of the inferior

Fig 2—Note the compression of the left parietal lobe by the large blood clot

parietal lobe and extended into the occiput. The compression caused by the blood clot had compressed the lateral ventricle and shifted the structures slightly past the midline. A great deal of blood was present in the subarachnoid space in relation to this large subdural clot.

Gross Diagnosis There were massive subdural hematomas (especially on the left side), moderate subarachnoid hemorrhage, compression and degeneration of the left parieto-occipital areas.

COMMENT

This case presents a number of unusual features. A spinal puncture was not done at the second admission in 1923 but in the light of our present knowledge the history is certainly suggestive of a subarachnoid hemorrhage. At the age of 11, the patient probably had another episode of intracranial bleeding treated at another institution. At the age of 13 and again at 22 he exhibited the classic symptoms of sudden spontaneous intracranial bleeding. With none of these attacks was there any history even suggestive of preceding trauma.

In view of the usually unsatisfactory response to treatment (including transfusions) noted so frequently in cases of hemophilia, it is amazing that this patient weathered three attacks of intracranial bleeding. Harper⁵ has reported recovery from a cerebral hemorrhage in a hemophilic patient aged 4 years.

Little if any mention is made in the various neurologic textbooks⁶ of intracranial bleeding in hemophilia. Priest⁷ has reported a case of acute spinal compression in hemophilia. Arbuse and Locascio⁸ discussed the neurologic manifestations of hemophilia. They stated that hemorrhages were usually single and post-traumatic but might be multiple. Bleeding was generally from the pial vessels, and central hemorrhages were more common than peripheral lesions.

It seems logical to conclude that this patient not only suffered a spontaneous intracranial hemorrhage as a complication of hemophilia but apparently survived three such crises. The final episode was characterized by massive spontaneous bilateral subdural hematomas.

SUMMARY

A hemophilic patient had multiple bilateral spontaneous intracranial hemorrhages. Death at the age of 22 was preceded by recovery from at least one and possibly three attacks of spontaneous subarachnoid bleeding.

SHOCK IN PHYSICALLY INDUCED FEVER THERAPY
TREATED WITH BLOOD PLASMA

LIEUTENANT ARTHUR M. PRUCE
MEDICAL CORPS ARMY OF THE UNITED STATES

This report on the use of plasma in the treatment of secondary shock following physically induced fever is presented because our armed forces have instituted a rapidly expanding program of fever therapy to treat venereal diseases. Shock is one of the more dangerous complications which may occur during or several hours after sustained high temperature rises induced by physical means. There are no significant differences in the picture of secondary shock whether caused by trauma, surgery or fever therapy. Although plasma has been widely and successfully utilized to combat shock from other causes, this appears to be the first report to describe its use in shock following fever therapy.

REPORT OF CASE

Private J. D. M., a Negro aged 20, was sent for fever therapy because of a chronic sulfonamide resistant gonorrhea of five months' duration. He had a moderately profuse urethral discharge. The prostate culture and urethral spread were positive. It was intended that he receive eight hours of therapeutic fever of between 106 and 106.7 F. The usual prefever routine was carefully observed. This routine included a thorough survey of the heart, lungs, kidney function, complete blood count and blood chemistry including determination of blood

sugar, nonprotein nitrogen and chlorides. Premedication consisting of the administration of 16 Gm of sulfathiazole, 4 Gm of calcium gluconate and 150 mg of ascorbic acid in divided doses was started three days prior to treatment. A final clinical check was made by a medical consultant, and the patient was accepted for treatment. Four cc of paraldehyde was given orally in the morning one hour before treatment was started.

At the onset of the treatment the only abnormality was a rapid pulse, 104 a minute. With a mean hypertherm cabinet temperature of 115 F, the patient's body temperature had attained the therapeutic level of 106 F in seventy-two minutes.

After three and one-half hours of fever at the therapeutic level of between 106 and 106.6 F by rectum, there was onset of headache and restlessness. The patient had taken fluids by mouth poorly and had vomited repeatedly—five times in the preceding two hours. To replace the fluid lost in vomiting and combat fluid loss in perspiration, 3,000 cc of 5 per cent dextrose in isotonic solution of sodium chloride was given intravenously during these three and one-half hours.

Oxygen was administered intermittently for the headache and restlessness, which are so often found to accompany this type of treatment and are the result of cerebral anoxia. During the following two hours of treatment the patient's restlessness increased. At the end of five and one-half hours of treatment his blood pressure fell to 78 systolic and 44 diastolic and the pulse rate rose to 156 and projectile vomiting developed. The sudden rise in the pulse rate and the fall in blood pressure indicated impending vascular collapse. This, together with continued evidence of cerebral irritation, forced discontinuance of the treatment.

To combat the impaired peripheral circulation and the possible cerebral edema, 40 cc of 50 per cent dextrose intravenously was twice given and continuous oxygen with the Boothby-Lovelace-Bulbunan mask was used. The blood pressure responded to this by a rise to 92/60 and the pulse dropped to 112. When the patient returned to his ward, his temperature was normal.

In the subsequent six hours in the ward his blood pressure rose to 110/60 and his pulse was regular, but the vomiting persisted. To combat this loss of fluids and chlorides by mouth he received 2,000 cc of saline solution intravenously. That evening at 9 o'clock, six hours after discontinuance of treatment, the patient went into shock, and his temperature fell to 96.7 F rectally. He became confused and then stuporous. The blood pressure fell to 80/52 and the pulse became thready and rose to 140 beats a minute. His respiratory rate jumped to 32.

Oxygen, with the patient in antishock position, 1,000 cc of 5 per cent dextrose in isotonic solution of sodium chloride intravenously and two doses of 50 cc of 50 per cent dextrose together with warm blankets were unsuccessful in relieving the shock. At this point trial use of blood plasma was advised. Two hundred and fifty cc of plasma was administered intravenously in fifteen minutes. A rapid change occurred in the clinical picture within the next twenty minutes. The patient's sensorium cleared, his blood pressure rose to 106/64, the pulse became regular and strong and fell to 80 beats a minute. His respiratory rate became normal and the rectal temperature rose to 98.6 F. This appears to be the first case in which plasma was used successfully to combat shock following physically induced fever therapy. Interestingly enough, the patient was cured of gonorrhea in spite of only five and three-quarters hours of therapeutic fever.

SUMMARY

Shock following physically induced fever therapy was successfully treated by the intravenous injection of 250 cc of blood plasma after the usual accepted antishock measures including intravenous isotonic solution of sodium chloride and hypertonic dextrose and oxygen had failed. This appears to be the first report on the use of plasma in shock from this form of treatment and emphasizes the importance of the use of plasma in the treatment of secondary shock from all causes.

MANSON'S SCHISTOSOMIASIS

CLINICAL LECTURE AT ATLANTIC CITY SESSION

ENRIQUE KOPPISCH, M.D.

SAN JUAN, PUERTO RICO

There are important reasons why physicians in all parts of North America should devote increasing attention to diseases of the tropics. First, many of those who in less tragic times would almost certainly never have seen service in tropical lands will sooner or later be confronted with such a contingency. Second, there can be little doubt that some of these diseases will be contracted by our soldiers and brought back with them as they return to the homeland on furlough or definitely.

As regards schistosomiasis, the problem with homecoming troops will probably be one mainly of diagnosis for the physicians of this country who may be called on to take care of such cases. From the public health point of view, no difficulties should perhaps be expected, for of the known planorbidis of the United States none have yet been proved, to my knowledge, capable of acting as intermediate host. One cannot, however, until an exhaustive survey is made, be certain that none of them can act in that capacity.

Of the three forms of schistosomiasis—the Oriental or Japanese, the vesical or urinary and the mansoni or so-called intestinal—I shall limit my discussion to the last named.

GEOGRAPHIC DISTRIBUTION

Manson's schistosomiasis is a disease of extended geographic distribution and of great importance as a morbidity and mortality factor in those regions in which it occurs endemically.

Africa, northern South America and the Caribbean region are the great endemic foci. In northern Africa it is found in the lower Nile Valley, particularly in the Delta, and in the Sudan. It is present along the East African coast from Zanzibar to below the Zambezi River, and in the island of Madagascar. In central Africa it occurs throughout parts of Tanganyika, the Belgian Congo and Rhodesia. To a limited extent it is present in Natal and the Transvaal. In West Africa it is seen in Senegal, French Guinea and, sparsely, as far as Lake Chad. Cases have been found in Liberia, Sierra Leone, Algeria, Harar (Ethiopia), Eritrea, southern Tunisia and Cyrenaica, but in these regions no important endemic zones have been encountered. There is a small endemic focus in Yemen, Arabia. In Egypt alone Scott¹ estimated in 1937 that there were 3,000,000 cases of Manson's schistosomiasis.

In the New World it occurs in parts of northern and northeastern Brazil, with a variable incidence which in one locality of the state of Minas Geraes has reached 85.18 per cent.² Total figures for Brazil are unknown. In Venezuela its distribution so far seems restricted to a limited part of the north central zone, where

according to Scott³ 60 to 80 per cent of the population in the valleys near Caracas are infected. The disease is fairly common in Dutch Guiana.

Among the islands of the Caribbean, schistosomiasis is present in Puerto Rico, Vieques, St. Martin, St. Kitts, Nevis, Monserrat, Antigua, Guadeloupe, Martinique and St. Lucia. In Puerto Rico, 14.6 per cent of the autopsies performed in San Juan, a nonendemic center with a population of about 170,000, have presented evidences of the disease.⁴

Its incidence is greatest among those in the second and third decades of life, but it affects the two sexes to about the same extent except in regions in which occupation or habits may result in more chances of exposure on the part of members of one sex.

LIFE CYCLE OF PARASITE

For the completion of the parasite's life cycle a specific intermediate molluscan host is necessary. In Puerto Rico, as in most of the endemic foci of the Western Hemisphere, the snail concerned is *Australorbis glabratus*. Given suitable climatic and hydrographic conditions, a miracidium is hatched when the human feces containing ova of *Schistosoma mansoni* reach the water. It swims about until it finds a snail of the appropriate species which it penetrates and parasitizes. Within the snail the miracidium undergoes morphologic alterations and great multiplication resulting, at the end of twenty-two to thirty-one days, in the emergence of large numbers of fork-tailed cercariae.

The disease is acquired through exposure to cercariae, usually while bathing in infected streams or working in irrigation canals, but infection can also take place through the buccal mucosa while drinking. The body of the cercaria penetrates by boring through the epithelium of either the skin or the mucous membrane, the tail dropping off as soon as the body secures a firm hold. After penetration, and until maturity is reached, the parasite is referred to as a metacercaria.

PREVALENCE

From what has so far been said of the life cycle and mode of infection, it is clear that spread of the disease can be avoided by (1) curing all who are affected with it, so that no more viable ova will pass with their feces, (2) preventing the contamination of bodies of water with human excreta, (3) exterminating the snails or cercariae, and (4) keeping the people away from the sources of infection. One or more or all of these methods may be applicable with success in a few communities, particularly in small ones, but in the larger endemic foci the density of population and extent of infested territory make these methods unpractical at the present time. Truly tangible results will perhaps not be forthcoming until education of the masses is much more advanced than at present, until medical care in tropical countries is more widespread and efficient and until the standard of living of the average individual in those areas is materially improved.

PATHOGENESIS, ENTRUSION OF OVA AND PATHOLOGY

The usual route of penetration is through the skin. Since the metacercariae are next found in the lung, it is clear that in the derma they must enter either lymphatics or veins. In experimental inoculations of

white rats with *Schistosoma japonicum* Watarai⁵ saw the parasites within both blood vessels and lymphatics. In the rabbit on the other hand, in an examination of more than 3,500 serial sections of skin taken from one to fourteen hours after exposure, at intervals of one hour, I⁶ found parasites only in lymphatics (fig 1) of the dermis. For man it is not exactly known which of the two routes is usually selected, but it is generally taken that they pass into veins.

The course followed by the metacercariae seems at all times to be strictly intravascular. Those which are not caught and destroyed in the pulmonary circulation reach the left side of the heart, whence they are ejected with the arterial blood to all organs and tissues. Some of them obstruct capillaries, giving rise to petechial hemorrhages, and a great many are undoubtedly lost during the period of wandering. Finally, those which reach organs and tissues whose venous drainage is by way of the portal vein seem to be the only ones that survive and establish a foothold in the mammalian host. By passing from the arterial to the venous side in organs like the spleen, pancreas, liver, stomach and small and large intestine, they reach intrahepatic portal branches, where they attain maturity. It seems probable that some of the parasites may pass through the liver and lungs more than once.

Fig 1—Cercaria in lymphatic next to a hair follicle of an experimentally infected rabbit four hours after exposure ($\times 400$). Originally published in the Puerto Rico Journal of Public Health and Tropical Medicine.⁶

Mature or almost mature males and females wander against the blood current and copulate in the larger venous tributaries of the portal vein, showing a strong and unexplained preference for the lower colonic and

rectal branches. For deposition of the ova, the females wander on, usually alone, into visceral venules which they fit snugly, thus usually taking place in the large intestine.

The mechanism by which ova pass from the blood vessels in which they are deposited into the tissues has been the subject of much controversy. With variations

Fig 2—Extension of endothelial lining of venule about schistosome ovum. Experimentally infected monkey ($\times 450$). Originally published in the Schweizerische Zeitschrift für Pathologie und Bakteriologie.¹¹

in certain details, most of the interpretations have been to the effect that the process is one of progressive accumulation of ova in a blood vessel the wall of which is ultimately ruptured thereby,⁷ of forceful ejection by pressure exerted by the blood,⁸ of ejection by the pressure exerted by movements of the tissues of the host,⁹ or of tearing of the wall by means of the spine of the ovum.¹⁰ According to our observations,¹¹ conducted on properly selected human and animal tissues sectioned serially, the ovum comes to lie against the endothelial lining of the venule in which it is laid or, in the case of the liver, to which it is carried with the blood stream. Immediately after this the endothelial cells extend from all sides by multiplication and cover the ovum completely, thus excluding it from the circulation (fig 2). An inflammatory reaction, to a minor extent exudative and mainly proliferative (pseudo-tubercle formation), then develops about the ovum, and the venule is either pushed aside or obliterated. The way in which it passes into the lumen of the intestine is not explained by these observations. It is possible that only ova that are laid immediately beneath the epithelium can ever reach the outside through areas of ulceration or of accidental abrasion, aided perhaps by the intestinal movements and the passage of the feces. My observations help me to understand why ova with a terminally placed spine (*Schistosoma haematobium*) and others with practically no spine (*S. japonicum*) leave blood vessels as readily as those of *S. mansoni* with its well developed lateral spicule.

It is probable that in man most of the damage is accomplished by the ova. The characteristic mode of reaction of the tissues in all organs to the presence of these structures is by the formation of a pseudo-tubercle. First polymorphonuclear leukocytes surround the ovum, if the embryo is still present (fig 3). Fre-

quently, however, the embryo has died and been absorbed by the time extrusion has taken place, and then the lymphocyte seems to be the first cell to appear about the egg shells. Soon after that, epithelioid and foreign body giant cells develop. The whole constitutes a microscopic nodule or pseudotubercle about the periphery of which lymphocytes, eosinophils and monocytes in variable proportions form a zone of infiltration. A peripheral layer of concentrically disposed fibroblasts next appears, and by the progressive broadening and condensation of this capsule the pseudotubercle is ultimately converted into a spherical fibrous nodule averaging 200-250 microns in diameter. The series of changes is shown in figures 4 to 6. These nodules are extremely helpful in histologic surveys of tissues in suggesting the presence of the disease, and careful examination will often disclose the faded remnants of a schistosome shell in their center. In endemic foci, minor grades of fibrosis of the portal spaces, especially when accompanied by eosinophilic infiltration, are likewise a signal for directing a careful search for pseudotubercles and ova. An easier and more certain way of establishing the presence of the disease post mortem in very light infections is to digest portions of the liver and wall of the rectum in 3 to 10 per cent sodium or potassium hydroxide diluting with water after digestion centrifuging and searching for the egg shells in the sediment.¹²

The presence of ova leads to progressive fibrosis of portal spaces and of the submucosa of the colon with ultimate development, if ova continue to be deposited in sufficient numbers over several years, of a portal cirrhosis and splenomegaly. As part of the cirrhosis there is portal obstruction, resulting in development of a collateral circulation of which an important complication is the formation of esophageal varices that not infrequently give rise to fatal hemorrhage. The heightened blood pressure in the splenic vein favors the development of sclerotic changes in its wall at times with calcification, and in a few cases thrombosis supervenes. In my material⁴ ova have been found microscopically in only 0.8 per cent of spleens in cases of schistosomiasis. This leads me to believe that ova

Fig. 3.—Section of human liver showing infiltration of polymorphonuclear leukocytes about ova ($\times 450$). Originally published in the Puerto Rico Journal of Public Health and Tropical Medicine.⁴

play no predominant part in the splenic enlargement which is probably due to two main factors—obstruction to the portal circulation by the cirrhosis, and a general response to the infection on the part of the reticulo-endothelial components of the organ.

In animals like the rabbit, on the other hand we have shown the important role played by the maturing and adult schistosome worms (in contradistinction to ova), in the development of certain pathologic changes, such as polypoid endophlebitis of the intrahepatic portal branches and pulmonary arteritis. These

changes are readily demonstrable for many days before the beginning of oviposition.

Exceptional aberrant localizations of worms and ova may produce a myelitis,¹³ salpingitis, oophoritis¹⁴ or pulmonary arteritis¹⁵ as a dominant part of the clinical or pathologic picture in man at any given time but in the great majority of cases the fundamental pathologic triad in this disease, when fully developed, consists of colitis, portal cirrhosis and splenomegaly. Jaffe¹⁶ of Caracas reports the finding of bilharzial myocarditis in his Venezuelan material, but I have as yet not encountered that complication in Puerto Rico nor do I find it mentioned in the literature from Africa and the remainder of South America.

In the gastrointestinal tract besides the colitis fistulas to the perineum and colonic and anal polyps may develop. Ova and pseudotubercles not infrequently will be found in the appendix and it seems as if in some cases this would give rise to symptoms referable

to that organ. In other cases ova are laid in large numbers in the mesentery or mesocolon, resulting in massive fibrosis and edema of those parts with formation of a tumor-like mass which may produce intestinal obstruction, it is fortunate that such cases are rare for they are very puzzling from the diagnostic point of view and quite hopeless from the therapeutic

CLINICOPATHOLOGIC FEATURES

The manifestations of the disease, both clinical and anatomic, may conveniently be grouped into three stages (1) an early period comprising penetration of the cercariae, migration within blood vessels and maturation in intrahepatic portal branches, (2) an intermediate period of progressive accumulation of ova in various organs and tissues and (3) a late period of frank visceral damage, mainly cirrhosis and splenomegaly.

Early Period—I am not aware of any pathologic studies describing the changes in the human host prior to the onset of oviposition, so one must try to surmise what happens in man from what obtains in animals experimentally infected. In the rabbit,⁶ changes are slight except in hyperinfections, in which event the animal may die prior to the onset of oviposition. Penetration produces a mild dermatitis of brief duration and an acute adenitis of the inguinal and axillary nodes, probably due to the passage of the metacercariae but conceivably also to bacteria brought in by the pene-

of rupture, petechiae develop and are found during the period of migration in all tissues but are always more numerous in the lung. Should the migrating parasite undergo extravasation in the lung, there is formed a limited area of eosinophilic and lymphocytic infiltration with or without foreign body giant cells. During the first week of infection the rabbit's spleen

trating cercariae. As the metacercariae pass through the pulmonary circulation, some capillaries become obstructed and even ruptured. In the former case a small focus of congestion and infiltration with eosinophils and a few round cells will result. In the case

reacts with congestion and pseudoeosinophilic infiltration. The liver, before the deposition of any ova, shows a portal phlebitis with round cell and eosinophilic response in the intima of these vessels and in the surrounding connective tissue; these alterations are diffuse but more pronounced about worms. Comparisons between different species are hazardous, however, and in later stages, at least, the hepatic alterations in the rabbit are rather different from those in man.

In man this early period usually is asymptomatic, exception being made of itching for a few hours over the parts exposed to the infested water. A history of well defined itching after falling into or bathing in a stream should always bring to mind this disease, and if the stream is known to be infested such a history should be taken as strong presumptive evidence of infection having actually taken place. According to Pons,¹⁷ some patients complain of anorexia, weakness, loss of weight, headache, nausea, vague intestinal symptoms, looseness of the bowels and either feverishness or short accessions of high fever. These symptoms have their onset a few days to two weeks after exposure, and not all of them may be present at a given time. Unfortunately, these manifestations have so far been

¹⁷ Pons J. A. Studies on Schistosomiasis Mansonii in Puerto Rico. V. Clinical Aspects of Schistosomiasis Mansonii in Puerto Rico. Puerto Rico J. Pub. Health & Trop. Med. 13: 171 (Dec) 1937.

studied in but few cases and, furthermore, it seems probable that they are present in the heavier infections only. Before ova begin to pass with the feces, there are no sure means of establishing the diagnosis.

Intermediate Stage—This is taken to begin with the onset of oviposition on or about the fortieth day after exposure. By this time all predestined wandering through the body has come to an end, and the worms have reached maturity.

The first well defined symptoms of this stage, and of schistosomal infection as a whole, begin at different times, according to different authors. Pons sets the beginning at thirty-nine to forty-five days after exposure. Girges¹⁸ at twenty-one to thirty-five and Lawton¹⁹ at twenty-eight to eighty-four days. The symptoms have an abrupt onset with fever, accompanied or not by a chill, having a remittent or intermittent course and reaching 102 or as high as 104 F daily. The duration is at least two or three weeks, probably longer when not cut short by treatment. The fever is accompanied by the usual symptoms of a febrile process by generalized or localized abdominal discomfort, with or without pain, which may be colicky, by nausea, vomiting, abdominal distention, dysenteriform manifestations, urticaria and cough, which can be hacking and persistent. Physical examination may disclose patchy areas suggestive of bronchopneumonia and enlargement of the spleen and liver. There may be severe eosinophilia with a low, normal or elevated leukocytic count.

Faust, Jones and Hoffman²⁰ found that ova of *S. mansoni* begin to appear, in the stools of monkeys experimentally infected, thirty-seven to forty-two days after exposure. In the rabbit and white rat I first encountered ova in sections of the liver on the fortieth day. As Pons¹⁷ well points out, the onset of the fever in his cases coincided quite precisely with the beginning of oviposition. From this time on large numbers of ova with their contained embryos are being deposited in the intestine and being carried to the liver. While some reach the intestinal lumen, many others are retained in the tissues, the embryo soon dies, often even while the ovum is still within a blood vessel, and the ova provoke an inflammatory reaction. The febrile period of this stage of the disease is best explained as part of the host's response to the ova and to the humoral phenomena, probably of allergic nature, incidental to the death and disintegration of large numbers of embryos. It is also highly probable that in cases in which these manifestations are present worms are passing to the lungs and giving rise to patchy areas of pneumonia.

Girges and Lawton set the onset of the febrile period at an earlier date than Pons, but this discrepancy might well be of no fundamental importance, for it is to be expected that in some cases, especially in the more heavily infected, the symptoms of the early stage may be so severe as to blend with those of the stage under discussion. The late onset given by Lawton, as up to the eighty-fourth day after exposure, is not readily explainable.

After the initial febrile period which does not occur in all cases, the clinical course is variable. If the infection has been slight symptoms are very mild or altogether lacking. Other patients will go through irregular periods of abdominal discomfort, of more or less severe, more or less prolonged diarrhea, often with blood in the stools. There may be further febrile accessions. The diarrhea may be accompanied by tenesmus and may alternate with periods of constipation. During times of quiescence both the diarrhea and the abdominal discomfort or pain may be provoked by dietary excesses or indiscretions, or by the ingestion of spirituous liquors. Frequently there is nothing very characteristic about the disease during the early part of this stage, and the spleen and liver may not be palpable for a number of years after onset. However, given the geographic possibility of infection having taken place in a given case, diarrhea with blood in the stools and obscure abdominal symptoms call imperatively for inclusion of the disease in the differential diagnosis. In this stage of the disease eosinophilia is a very frequent finding and of great value in calling the observer's attention to a parasitic illness.

Not enough emphasis can be laid on the importance of establishing the diagnosis at this stage and the earlier the better. Failure to do so and to carry on treatment will seal the patient's fate or condemn him to prolonged ill health.

During this time a chronic colitis with alternating phases of acuteness and quiescence is being established. The mucosa may show extensive superficial ulceration, and sometimes polyps or fistulas will form. The ova which are being swept from intestinal venules into the liver are caught in the portal venules and do their damage in the portal spaces. The splenic enlargement at this stage is due to congestion secondary to the portal fibrosis, and to reticuloendothelial hyperplasia.

The gravity of the symptoms and the outcome of the disease depend on how heavy the infection has been and on whether oviposition can be stopped through treatment by destroying the adult worms before the hepatic fibrosis has developed into a true cirrhosis. It is usually a matter of ten or twelve years before frank cirrhosis develops.

Late Stage—This has been previously defined as the stage of frank visceral damage. It is obvious that, for a given case, the classification will depend on what the observer would consider frank damage. According to my conception of this disease, the main criterion in the average case of schistosomiasis should be the question of whether or not hepatic cirrhosis is already present. Aberrant localizations of ovipositing worms may at any time give rise to such frank visceral damage as oophoritis or salpingitis, but these are complications which may appear quite early in the course of the disease and, if diagnosed in time, should be amenable to treatment. The colitis itself, which may constitute a prominent part of the clinical picture from very early in the course, should not, unless grossly misdiagnosed and neglected, decide the outcome of the disease. Bilharzial pulmonary arteritis and bilharzial myelitis are grave but rare manifestations and constitute complications rather than an integral part of the natural history of the malady. The average patient with uncomplicated schistosomiasis in the late stage will as a rule succumb to hepatic cirrhosis, and it is the condition of the liver that decides the prognosis.

19 Lawton, F. B. *Schistosomum Mansoni: Early Clinical Features of the Disease*. Publication by Commonwealth of Australia Department of Defense. 1917. p. 11.

20 Faust, E. C., Jones, C. A. and Hoffman, W. A. *Studies in Schistosomiasis Mansoni in Puerto Rico. III. Biologic Studies. 2. The Mammalian Phase of the Life Cycle*. Puerto Rico J. Pub. Health & Trop. Med. 10: 133 (Dec.) 1934.

In the late stage the clinical picture is dominated by the manifestations of cirrhosis with splenomegaly, ascites, anemia and cachexia. Diarrhea may still occur in bouts, but it may be altogether absent for long periods. Vague abdominal symptoms and pain of variable intensity referred to some part of the colon usually persist. At any time during this stage there may come accessions of fever lasting from a few days to several weeks. Eosinophilia may persist in some cases while in others it is lacking. Ova are often absent from the stools, not so much in our opinion, because of fibrosis of the intestinal wall as because by this time the disease has lasted for many years and the number of ovipositing worms has become greatly reduced. The clinical picture may be the exact duplicate of Laennec's cirrhosis or it may mimic the Banti syndrome when, as not infrequently happens, there is anemia with leukopenia. Hematemesis is of frequent occurrence and may be the first indication of cirrhosis, not infrequently it is the immediate cause of death.

The diagnosis at this stage depends on the clinical history, on the presence of eosinophilia, on repeated search for ova in the stools utilizing methods of concentration and, lastly, on exploratory laparotomy with biopsy of the liver. Fairley's complement fixation²¹ and cutaneous²² tests, as well as Tahaferro's precipitin test,²³ hold great promise as aids in diagnosis. It is unfortunate however, that since they have not yet been applied in large numbers of cases their limitations and pitfalls are not fully known.

Once cirrhosis is well developed, it is probable that the establishment of the diagnosis becomes of little more than academic interest. Certainly, some symptoms like those of colitis may be very favorably influenced by judicious treatment even in the far advanced cirrhotic case, but practically no effect will be exercised on the hepatic process, which will continue to progress relentlessly even after the parasites are destroyed.

Pathologically, the cases in the late stage usually present but little evidence of acute colitis. This will depend on how active the infestation was at the time of death. If, as obtains in many cases, there had been no recent reinfections, and ten or fifteen years had elapsed since the last one, the number of worms encountered will be small or preponderantly of one sex, with the result that the number of ova reaching the large intestine has by this time become greatly reduced. Some fibrosis of the submucosa in the sigmoid and rectum will, however, usually be demonstrable and ova or empty egg shells, some of them calcified, will be found microscopically, mainly in the mucosa and submucosa.

The liver may be large, small or normal in size. It is always dense and pale with a surface that is usually finely nodular and only exceptionally coarsely nodular. On section the principal characteristic is the concentration of the fibrosis about the larger portal branches. When this feature is well developed there are distinct collars of white or pink connective tissue about these veins—the so-called pipestem type of cirrhosis of Symmers²⁴. Once I encountered, in a man aged 24,

a greatly deformed liver with all the external appearances of a *hepar lobatum*. Yet in this case there was no indication that syphilis was present, so that the possibility that schistosomiasis may at times duplicate the gross external appearance of late syphilis of the liver ought to be kept in mind. Microscopically, there is diffuse scarring of portal spaces with formation of pseudotubercles about ova, diffuse and focal infiltration with lymphocytes, plasma cells and eosinophils and more or less pigmentation of Kupffer's cells and phagocytes in the periportal tissues, with finely divided brown pigment which is opaque when viewed with the compound microscope without Nicol prisms.

The spleen may not be enlarged, even when there is advanced cirrhosis, but this is exceptional, splenomegaly being the rule. The spleen in cases in the late stage is characterized by a diffuse fibrosis of the pulp which ultimately results in great reduction in the number of cells in Billroth's cords and a diminution in the size

and number of lymphoid follicles. Brown pigment is usually found in the reticuloendothelial cells of the organ.

This pigment is elaborated by the adult worms from the hemoglobin of the blood they ingest and is excreted into the portal blood. It is, therefore, taken up first, and in larger quantities by the reticuloendothelial components of the liver and also by similar cell elements in the spleen, bone marrow and mesenteric lymph nodes. The pigment cannot be differentiated by its location appearance under the microscope or microchemical constitution from malarial pigment. We believe that if due caution is exercised in ruling out the presence of malaria, the presence or absence of pigment, especially in the liver, can be utilized as a valid criterion in post-mortem studies as to the presence or absence of living worms and the degree of activity of the schistosomal infection at the time of death. If found, it must mean that there still were living worms within the host, but it cannot be interpreted as meaning that oviposition was still taking place, for the worms remaining in the late cases may all belong to the same sex. The only criterion for activity of oviposition is the finding of embryos within ova.

The distribution of schistosome ova in the various viscera in which they were encountered by microscopic examination in 147 cases of the disease is given in table 1, based on a table from a previous work.⁴ The

cases appear subdivided into three groups: minimal, moderately advanced and severe. The minimal cases had had very light infections. The moderately advanced correspond to the intermediate stage of the present classification and the severe to the late stage. The last mentioned group, however, includes 2 fairly early cases (no frank cirrhosis) of extremely heavy infection, and 1 in which death was due either to treatment with fuadin or to pulmonary bilharziasis or both. With the method used (search for ova in routine microscopic sections) the liver, colon and rectum were found to contain ova in about the same proportion in all cases. From what is known of the habits of oviposition of the worm and to a lesser extent from actual observation of sections it seems certain, however, that more ova are present in the large intestine in a given case than in the liver. Second, when the infection is older and heavier, ova are invariably found in both the liver and the colon and furthermore, they appear in viscera that are not involved when the infection is lighter or of shorter duration. This is natural, for the longer the duration and the heavier the infection, the larger the number of ova that will accumulate and the greater the chances for wandering of worms or sweeping of ova by the blood stream to unusual situations.

Thus in some instances ova will be encountered in the urinary bladder, ovary, fallopian tube, uterus, testes

or prostate. The known intercommunications existing between the inferior hemorrhoidal vein plexus and the various pelvic plexuses explain the possibility of such localizations. Through the inferior hemorrhoidal plexus also parasites and ova may be taken up the inferior vena cava to the right side of the heart and lungs. For the schistosomal myelitis that has been described in a few instances, the explanation is not very apparent. Muller and Stender,¹³ who saw 1 case, believe that the parasites pass from the vesical to the pelvic vein plexus and thence, by way of the lumbar, azygos and hemiazygos veins, to the veins of the anterior portions of the spinal cord. Espin,¹³ on the other hand, believes that in his case the parasite or parasites passed from the liver by way of the hepatic artery, celiac trunk and abdominal aorta to a lumbar artery, through which the anterior spinal artery was reached. The question must remain unanswered until additional cases afford a better opportunity for analysis. It seems to me, however, from what is known about the habits of the parasite, that prolonged sojourn in arteries other than the pulmonary is probably not possible for this parasite and that a prolonged journey against the strong arterial current seems highly improbable. From the pelvic plexuses of veins the parasites ought to be able to pass rather readily to the vast vertebral plexus² from where they could reach the tissues of the spinal cord for oviposition, much as in the abdominal organs.

In our postmortem material the ultimate cause of death was hematemesis due to a ruptured esophageal varix in one third of the advanced fatal cases, cachexia due to cirrhosis in another third and complications in the remainder. The fatal complications were hyperinfection, partial intestinal obstruction from schistosomal fibrosis of the mesocolon, colloid adenocarcinoma of the cecum, fistula of the ascending colon with formation of a large retroperitoneal abscess, and pulmonary bilharziasis.

The importance of the role played in Puerto Rico by schistosomiasis as an etiologic factor of hepatic cirrhosis is well demonstrated by the analysis made in table 2 of consecutive autopsies performed in San Juan which, as previously mentioned, is not an endemic focus of the disease.

It is thus seen that schistosomiasis was the cause of the cirrhosis in fully one third of the cases.

There are certain differences between the clinical picture of this disease, as I have briefly described it from what I have seen of it in Puerto Rico, and the descriptions of Manson's schistosomiasis in Egypt. I refer particularly to the relative prominence in that country of papillomatous formations, especially in the lower part of the rectum, and of symptoms of colitis without cirrhosis. In the first place I am fairly certain that in Puerto Rico, with the exception of small groups of the population in a few endemic foci, the infection on the average is milder than in Egypt. This seems due to differences in the habits of the population and in certain socioeconomic factors between the two countries. In other words, the chances of infection and repeated reinfection with heavy doses seem to be much greater in the case of the Egyptian fellahs than in that of the Puerto Rican jíbaro. Such being the case one can expect intestinal manifestations to be more severe and prominent in Egypt than in Puerto Rico and the intermediate stage to be more frankly dominated by symptoms of colitis. If to this is added the greater difficulty encountered in Egypt for case finding and follow-up, because of the vastly larger numbers of the population that are infected in the Nile Delta as compared with those in Puerto Rico, one can well imagine that the number of patients who go untreated or insufficiently treated must be greater than in Puerto Rico.

COMMENT

I have endeavored in the course of this presentation to emphasize certain aspects of the disease that seem to me of considerable importance. First, my view that as regards the final outcome of the average case of Manson's schistosomiasis the all important indication is to establish the diagnosis and institute treatment before the onset of cirrhosis. Second, even though at a given time in the course of the disease the presenting symptoms may be mainly referable to some organ (colon, lung, spleen) other than the liver, ova are constantly accumulating in the latter organ and producing a fibrosis which will in time give rise to an irreversible cirrhosis. Third, schistosomiasis should be thought of whenever, in an individual who has lived or sojourned in an endemic focus of the disease, there are abdominal complaints of any kind, hepatosplenic enlargement, fever with eosinophilia, evidences of cirrhosis or a Banti syndrome. Lastly, it may require a searching history, repeated fecal examinations by methods of concentration and even exploratory laparotomy with biopsy of the liver for the presence or absence of the disease to be firmly established.

Council on Foods and Nutrition

THE ENRICHMENT OF FLOUR AND BREAD RECOMMENDED BY THE FOOD AND NUTRITION BOARD OF THE NATIONAL RESEARCH COUNCIL AND IN THE CASE OF FLOUR NOW RECOGNIZED OFFICIALLY BY THE FEDERAL FOOD AND DRUG ADMINISTRATION FOLLOWS CERTAIN POLICIES WHICH PREVIOUSLY WERE ADVOCATED BY THE COUNCIL (ANNUAL MEETING OF THE COUNCIL ON FOODS AND NUTRITION THE JOURNAL AUG 19 1939 P 680) THE COUNCIL FOR SOME TIME COGNIZANT OF THE DISADVANTAGE IN THE LOSS TO THE DIET OF THIAMINE (VITAMIN B₁) BROUGHT ABOUT BY THE EXTENSIVE USE OF HEAVILY MILLED WHITE FLOUR ANNOUNCED IN 1939 THAT IT WOULD REGARD WITH FAVOR THE RESTORATIVE ADDITION OF THIS AND OTHER VITAMINS TO WHITE FLOUR IT THEREFORE HAS BEEN PLEASED TO SET THE SUCCESSFUL APPLICATION OF THIS POLICY IN THE RAPIDLY EXTENDING USE OF ENRICHED FLOUR AND ENRICHED BREAD LATE REPORTS INDICATE THAT NO LESS THAN 70 PER CENT OF ALL FAMILIAL GRAIN WHITE FLOUR AND BAKERS WHITE BREAD HAD BEEN ENRICHED BEFORE THE END OF 1942 AN ORDER OF THE RECENTLY CREATED FOOD DISTRIBUTION ADMINISTRATION REQUIRED ENRICHMENT OF ALL BAKERS WHITE BREAD AFTER JANUARY 18 1943

SUBSTITUTION OF ENRICHED FOR UNENRICHED WHITE BREAD INCREASES THE THIAMINE INTAKE PROVIDED BY THE 'AVERAGE' DIET OF 2500 CALORIES FROM SOMETHING LESS THAN 0.9 TO APPROXIMATELY 1.3 MG PER DAY (HANE R J JOHNSON ELIZABETH AND WILLIAMS R R J NUTRITION 23 613 [JUNE] 1942) IF LIQUID SKIMMED MILK IS USED IN PLACE OF WATER IN MAKING BREAD OR AS HAS BECOME A COMMON BAKERS PRACTICE IF 6 PARTS OF DRIED SKIMMED MILK SOLIDS FOR EACH 100 PARTS OF FLOUR IS ADDED TO THE DOUGH THE RIBOFLAVIN CONTENT OF THE RESULTING BREAD COMPLIES WITH PROPOSED STANDARDS FOR ENRICHED BREAD

EVIDENCE OF THE NUTRITIONAL SIGNIFICANCE OF THESE SMALL ADDITIONAL DAILY INCREMENTS OF THIAMINE AND RIBOFLAVIN IS PRESENTED IN THE FOLLOWING SPECIAL ARTICLE AUTHORIZED FOR PUBLICATION BY THE COUNCIL.

FRANKLIN C BING Secretary

EVALUATION OF NUTRITIVE CONTRIBUTION OF ENRICHED WHITE FLOUR

RAY D WILLIAMS, MD
Fellow in Medicine

HAROLD L MASON PhD
AND

RUSSELL M WILDER, MD
ROCHESTER, MINN

The nutritive contributions of diets in which the bread component was made of enriched white flour plain white flour and whole wheat flour respectively have been studied, with particular reference to satisfaction of human requirements for thiamine and riboflavin. We have not had experience with the analytic methods for determination of niacin—also a constituent of enriched flour—and consequently were limited to noting the presence or absence of symptoms of abnormality attributable to deficiency of niacin in deciding whether requirements for niacin were satisfied. The standard diet when the flour used was plain white flour, provided approximately 0.22 mg of thiamine, 0.35 mg of riboflavin and 2.5 mg of niacin per thousand calories. This degree of restriction of thiamine, riboflavin and niacin is probably not greater than obtains frequently in the diets of certain population groups of the United States.

METHODS OF STUDY

Women who volunteered were transferred to the nutrition division of the hospital and provided with a diet supplemented so that satisfactory tissue stores of thiamine and riboflavin and of other members of the vitamin B complex were assured. During this foreperiod the subjects received their preliminary examinations and were familiarized with the routines and procedures of the ward. After this period of preliminary observation seven of the women were chosen for

study. Selection was made on the basis of absence of significant physical or emotional defects, absence of evidence of abnormal nutrition, and willingness and ability to cooperate. Moderate supervised activity was permitted—such as housekeeping, laundering and sewing.

The standard diet was composed of foods which commonly appear on American tables. The flour in the diet of 2 subjects (1 and 2) was plain, unenriched white flour—flour 1. The diet of these subjects contained by analysis approximately 0.22 mg of thiamine and 0.35 mg of riboflavin per thousand calories. The flour in the diet of 3 subjects (3, 4 and 5) was the same flour which had been enriched by the addition of 2.5 mg of thiamine, 18.0 mg of niacin and 27.3 Gm of nonfat milk solids¹ per pound (454 Gm)—flour 2. The diet in which the flour was thus enriched contained by analysis approximately 0.45 mg of thiamine and 0.45 mg of riboflavin per thousand calories. The flour in the diet of the last two subjects (6 and 7) was a whole grain wheat flour—flour 3—which by analysis contained 2.19 mg of thiamine and 0.66 mg of riboflavin per pound of flour (flour 3). The diet of these subjects contained by analysis approximately 0.45 mg of thiamine and 0.45 mg of riboflavin per thousand calories.

The calories of the diet approximated 2250, the carbohydrate 327 Gm, the protein 67 Gm and the fat 75 Gm. Flour contributed about 30 per cent of the calories, and sucrose and other vitamin free constituents about 15 per cent. Caloric intake was adjusted to the requirement of the individual subject by giving fractions or multiples of the diets. By this method the ratios of thiamine to calories and of riboflavin to calories were maintained nearly constant.

No supplementary provision was made for any part of the vitamin B complex, but to assure adequacy of calcium, phosphorus, iron, ascorbic acid, vitamin A and vitamin D these nutrients were provided daily as tribasic calcium phosphate 0.6 Gm, ferrous sulfate 0.2 Gm, ascorbic acid 80.0 mg and halibut liver oil fortified with irradiated ergosterol 0.2 Gm (providing 10,000 U S P units of vitamin A and 4,000 U S P units of vitamin D).

Our methods of study of thiamine and riboflavin nutrition have been presented in earlier reports. Briefly, physical and neurologic examinations, determinations of proteins, calcium and phosphorus in the serum, blood counts, determinations of pyruvic acid², lactic acid³ and dextrose⁴ in the blood after oral administration of dextrose (Eaton-Rose dextrose tolerance test)⁵ and basal metabolic rates were made during a period of preliminary observation, again at intervals during an experimental period and finally during an after period. Electrocardiograms were taken approximately every two months. Estimates of gastrointestinal

1 A common practice of commercial bakers is to add 6 pounds of dry defatted milk solids to each hundred pounds of flour. (This amount of milk provides enough riboflavin to make the riboflavin content of the mix near to that of a mix made of whole wheat flour.) Enriched bread complies with proposed standards for riboflavin content when it is made with this amount of flour containing skim milk solids.

motility were made by taking roentgenograms a half, one two, three and five hours after administration of a meal of barium sulfate. During determination of gastrointestinal motility the subjects were maintained in the postabsorptive state and in the sitting or standing position for the period of five hours.

Urine was analyzed for content of thiamine by the thiochrome method of Hennessy⁷ and for riboflavin by the fluorometric method of Ferrebee⁸ each week. An excretion of less than 100 micrograms of thiamine in twenty-four hours was considered indicative of an unsatisfactory intake of thiamine.⁹ In the study here reported a test dose of 1.0 mg of thiamine hydrochloride and 20 mg of sodium riboflavin was injected subcutaneously once every month with determination of excretion for the ensuing four hours. These tests were performed with the subjects in the postabsorptive state. Excretion of less than 200 micrograms of thiamine in four hours after injection of a test dose of 1 mg was

by the fact that they were essentially relieved by later administration, May 16 to 31, of thiamine only. Physical evidence of deficiency of riboflavin or of niacin was not detected. However, the tongue of 1 subject (1) became somewhat reddened after four months, although the subject did not complain of soreness.

OBSERVATIONS ON SUBJECTS RECEIVING ENRICHED WHITE FLOUR (SUBJECTS OF GROUP 2)

The period of maintenance on the basal diet began Sept 12, 1941 and ended May 31, 1942 (263 days). Signs or symptoms of nutritional deficiency disease were never clearly in evidence among subjects of this group. However, in subjects 3 and 5 low excretions of thiamine for twenty-four hours and somewhat unsatisfactory excretions of test doses of thiamine were encountered. In periods when excretions were lowest, mild complaints of anorexia and weakness were voiced and the subjects occasionally were somewhat irritable and quarrelsome. Additional evidence that the intake of thiamine was not enough for entirely satisfactory nutritional status appeared from moderately abnormal elevations of pyruvic acid in the blood after administration of dextrose. That this mild abnormality was caused by deficiency of thiamine is indicated by the fact that administration of 15 mg of thiamine hydrochloride daily in the period May 16 to May 31, 1942 was associated with its correction. The presence of mild metabolic defect, excretions of less than 100 micrograms in twenty-four hours and excretions of less than 200 micrograms in four hours after administration of a test dose of 1 mg of thiamine constitute evidence which, as we have discussed in another paper,¹⁰ suggests that 0.45 mg of thiamine per thousand calories is something less than a satisfactory intake of this vitamin.

Likewise the excretions of riboflavin for twenty-four hours and for four hours after a test dose of 2 mg of riboflavin were somewhat low, indicating some degree of depletion of tissue stores of riboflavin. However, abnormalities of the skin, the eyes and the tongue characteristic of riboflavin deficiency did not develop.

OBSERVATIONS ON SUBJECTS RECEIVING WHOLE WHEAT FLOUR (SUBJECTS OF GROUP 3)

The period of maintenance on the basal diet began Sept 12, 1941 and ended May 31, 1942 (263 days). One subject (6) complained of weakness and mild loss of appetite after 100 days. These conditions were associated with some reduction of activity. At about this time excretions of thiamine fell to less than 100 micrograms in twenty-four hours and excretions after the test dose of thiamine fell to less than 200 micrograms. At about the two hundredth day this subject complained of numbness and tingling of the medial surfaces of the legs. The condition did not progress during the ensuing sixty days. That the complaints had basis in biochemical defect is indicated by values for pyruvic acid in the blood after administration of dextrose. The biochemical defect was corrected when 15 mg of thiamine hydrochloride daily was provided in the period May 16 to May 31, 1942.

The nutritional status of the second subject of this group (7) continued better throughout the period of study than that of the other subject of this group, and also better than that of subjects of group 2. The ordinary excretions of thiamine and riboflavin were higher and excretions after test doses of thiamine and riboflavin indicated that depletion of tissue stores of thiamine and of riboflavin was minimal. Possible

A comparison of intakes of thiamine and riboflavin by experimental subjects with minimal requirements (suggested by our own data) of thiamine and riboflavin and with allowances recommended by the Food and Nutrition Board of the National Research Council (dotted line).

considered indicative of depletion of tissue stores of this vitamin.¹⁰ We are as yet not ready to make comparable evaluations for excretions of riboflavin.

OBSERVATIONS ON THE SUBJECTS RECEIVING PLAIN UNENRICHED WHITE FLOUR (SUBJECTS OF GROUP 1)

The period of maintenance on the basal diet began Sept 12, 1941 and ended May 31, 1942 (263 days). Signs, symptoms and metabolic defects suggestive of deficiency of thiamine developed within 100 days. The deficiency syndrome was not essentially different from the syndrome of chronic, moderate restriction of thiamine which we previously have described.¹¹ That the signs, symptoms and metabolic defects observed were caused principally by deficiency of thiamine is indicated

explanations are better initial stores of thiamine and riboflavin lower requirements for them or better utilization of ingested vitamins. This subject was the youngest and most robust of the subjects of all three groups.

COMMENT AND SUMMARY

Adult human subjects were maintained for a period of nearly nine months (263 days) on a diet which contained 170 Gm (6 ounces) of ordinary white flour, which provided approximately 0.2 mg of thiamine and 0.35 mg of riboflavin per thousand calories. It was constructed of foods which commonly appear on American tables. Every subject received each day lean beef 100 Gm or beef 75 Gm and cottage cheese 35 Gm, canned carrots or beets or corn 50 to 75 Gm, lettuce or celery 30 Gm, tomatoes 75 Gm or lemon juice 20 Gm, canned pineapple 80 Gm or applesauce 100 Gm or dried sulfured apricots 30 Gm, butter 45 Gm, cream (35 per cent butterfat) 75 Gm, flour used in bread, cake or for other purposes 170 Gm and sugar as such or used in cake, jelly or candy 100 Gm. The calories closely approximated 2,250, the carbohydrates 327 Gm, the protein 67 Gm and the fat 75 Gm. The flour contributed about 30 per cent of the calories, and the sugar and other vitamin free constituents about 15 per cent. Thiamine deficiency disease developed, evidenced by clinical signs and symptoms, low excretions of thiamine and abnormal elevations of pyruvic acid in the blood after oral administration of dextrose.

Other subjects maintained on a regimen which was identical in every respect to the diet described, with the exception that the quota of flour was an enriched flour, to which furthermore 6 parts of skim milk solids was added for each 100 parts of flour—a common bakers' practice—maintained a nutritional status which was reasonably satisfactory. Signs, symptoms and metabolic defects suggestive of thiamine deficiency of an exceedingly mild degree were, however, observed. These subjects as far as could be determined, at the end of the period of study were in as good a physical status as the subjects of a third group who received the same diet, with the exception that the quota of flour was a whole grain flour.

The clinical courses, the excretions of thiamine and riboflavin and the apparent biochemical status of subjects who received either the flour with thiamine, niacin and nonfat milk solids added or the whole grain flour were very much better than the courses and status of the subjects who received the ordinary white flour.

The conclusion seems to be fully justified that a flour which contains, as a minimum, 20 mg of thiamine and 150 mg of niacin per pound (454 Gm) with 6 parts per hundred of nonfat milk solids is nutritionally a satisfactory food.

A further comment appears justified. Estimates based on disappearance of flour in the United States, exclusive of exported flour, indicate that the average per capita consumption of flour daily approximates 6.5 ounces (185 Gm) and that this contributes about 25 per cent of the calories of the average diet. Similar estimates based on disappearance of sugar indicate that the consumption of sugar per capita daily approximates 3 ounces (85 Gm) and that sugar thus contributes from 13 to 17 per cent of the calories of the average diet. In the diets used in the experiments here reported, the contribution of flour, sugar and other vitamin free constituents to the total calories approxi-

mated 30, 10 and 5 per cent respectively. From these estimates and from the experimental results it would appear that the average American diet, when its flour quota is plain, unenriched white flour, provides an insufficient amount of thiamine except when its foods other than its content of flour and sugar are selected with greater care than probably is customary. Restorative enrichment of white flour with thiamine to whole wheat levels helps greatly to correct this defect, whereas comparable enrichment with riboflavin, namely to whole wheat levels, will not correct the deficiency of the average diet in riboflavin (as shown in the accompanying chart). Our experiment was not designed to provide similar information about nicotinic acid (niacin).

Council on Pharmacy and Chemistry

NEW AND NONOFFICIAL REMEDIES

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED AS CONFORMING TO THE RULES OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO NEW AND NONOFFICIAL REMEDIES. A COPY OF THE RULES ON WHICH THE COUNCIL BASES ITS ACTION WILL BE SENT ON APPLICATION.

AUSTIN E. SMITH, M.D., Secretary

OVARIES (See New and Nonofficial Remedies, 1942, p. 373)

The following dosage form has been accepted.

THE LAKESIDE LABORATORIES, INC., MILWAUKEE

Solution of Estrogens (in oil) 10 cc rubber stoppered vials. Each cubic centimeter contains the equivalent of 20,000 international units of estrone and 0.5 per cent of chlorobutanol as a preservative in sesame oil.

NIKETHAMIDE (See the Supplement to New and Nonofficial Remedies, 1942, p. 17)

The following dosage form has been accepted.

THE LAKESIDE LABORATORIES, INC., MILWAUKEE

Ampul Solution of Nikethamide 25% W/V 1½ cc 0.5 per cent chlorobutanol added as a preservative.

PYRIDOXINE HYDROCHLORIDE (See New and Nonofficial Remedies, 1942, p. 563)

The following dosage forms have been accepted.

THE UPJOHN COMPANY, KALAMAZOO, MICH.

Tablets Pyridoxine Hydrochloride 10 mg

Ampoules Sterile Solution Pyridoxine Hydrochloride 50 mg in 2 cc

JOHN WILEY & BROTHER, INC., PHILADELPHIA

Tablets Pyridoxine Hydrochloride 25 mg

Ampoules Solution Pyridoxine Hydrochloride 50 mg in 1 cc

RIBOFLAVIN (See New and Nonofficial Remedies, 1942, p. 559)

The following dosage forms have been accepted.

THE WALKER VITAMIN PRODUCTS, INC., MOUNT VERNON, N. Y.

Tablets Riboflavin 1 mg and 5 mg

SODIUM MORRHUATE (See New and Nonofficial Remedies, 1942, p. 290)

The following dosage forms have been accepted.

GEORGE A. BREON & COMPANY, INC., KANSAS CITY, MO.

Solution of Sodium Morrhuate 5% with Benzyl Alcohol 2% 5 cc vials. Each cubic centimeter contains sodium morrhuate 0.05 Gm (¾ grain) and benzyl alcohol 0.02 Gm (⅓ grain) in aqueous solution.

BURROUGHS WELLCOME & CO., INC., NEW YORK

Hypoloid (Ampoule Solution) Sodium Morrhuate 5%, 2 cc. Each cubic centimeter contains sodium morrhuate 0.05 Gm and 0.5 per cent of phenol as a preservative.

THE SAFETY OF POOLED HUMAN PLASMA

In a discussion of the toxicity of human plasma a few months ago,¹ THE JOURNAL called attention to the results of observations on the intravenous injection of unpooled plasma by Levine and State.² Their work dealt with unpooled or monovalent plasma, the conclusion that there is "a correlation between skin sensitivity to the plasma and reactions after plasma transfusions" is not applicable therefore to pooled plasma. The authors themselves state that "it is not known what pooling of plasmas will do toward the elimination of transfusion reactions."

In the meantime the excellent results in the clinical use without preliminary tests, of plasma indicate that pooling under standard requirements, perhaps by mere dilution, inactivates substances—antigens, haptens, antibodies—that may be present in individual samples of plasma. Possibly also the introduction from without of harmful substances is prevented by the method of preparing pooled plasma. It should not be overlooked that general reactions may follow almost any kind of intravenous injection, e. g. saline solution of dextrose, owing perhaps to the presence of nonspecific, pyrogenic substances. Polayes and Squillace³ attributed chill and shock in a woman with postpartum hemorrhage to the intravenous injection of a solution of dried human plasma. While it is not absolutely certain that the plasma used was or was not pooled, account was not taken of the injection of 1,000 cc of 10 per cent dextrose in saline solution shortly before the plasma was given. The conclusion that the reaction was due to plasma is open to challenge because it may have been caused by the dextrose solution.

¹ Toxicity of Human Plasma editorial J A M A 120 206 (Sept 19) 1942

² Levine Milton and State David Skin Sensitivity to Human Plasma Science 96 68 (Jul 17) 1942 A and B Substances as a Cause of Reactions Following Human Plasma Transfusions J A M A 120 275 (Sept 26) 1942

³ Polayes S H and Squillace J A Near Fatal Reaction to Transfusion with Dried Human Plasma Solution J A M A 118 1050 (March 28) 1942

From a careful analysis of extensive data, Thallmer⁴ concludes that in pools of plasma or serum, agglutinins are reduced to such a low level "that no danger can result to patients from the injection of even large doses of these pools." Large amounts of pooled plasma are given safely without any preliminary tests for compatibility. The demonstration of the surpassing value of pooled human plasma in shock has been designated "a major medical victory."

PROPAMIDINE IN CHRONIC WOUND INFECTION

A series of aromatic diamidines prepared by Ewins was found by Lourie and Yorke¹ to possess activity against protozoal organisms as well as antimicrobial action. From the consideration of the chemical structure of these compounds it was expected that their antibacterial effect would not be inhibited by p-aminobenzoic acid as is the case with the sulfonamides. Thrower and Valentine² point out that sulfathiazole in a minimal concentration of 1/32,000 exerted an antibacterial effect and that this effect was completely inhibited by the addition of 1/10,000 to 1/1,000,000 of p-aminobenzoic acid. Propamidine, however, was unaffected by the p-aminobenzoic acid in the same dilutions and exerted an antibacterial effect at the minimal effective concentration of 1/128,000 in both cases.

In vitro experiments indicated that 4,4'-diaminodiphenylpropane dihydrochloride (propamidine) possesses a bacteriostatic activity against *Staphylococcus aureus* of the same order as sulfathiazole. The bactericidal activity of this drug appears to be equal to its bacteriostatic activity. Effective concentrations of this substance did not inhibit phagocytosis or cause hemolysis, and the bactericidal effect was not seriously lessened by the presence of pus. Clinical application of propamidine in 50 cases demonstrated that a concentration of 0.1 per cent of the drug in a 4.5 to 5 per cent strength of a watery methyl cellulose jelly will clear an infected area of dangerous organisms within ten days. Long application may lead to a mild superficial necrosis and to a relapse in the bacteriologic picture. The general efficacy of the preparation was demonstrated by the rapid improvement noted in all the cases. The wounds treated had often remained infected for months—sometimes for more than a year. The regular response to the application of the jelly could not have been due to chance.

McIndoe and Tilley³ report 11 cases of persistent hemolytic streptococcus infection in which other methods had failed and in which 0.1 per cent propamidine

⁴ Thallmer William Intravenous Injections of Pooled Normal Plasma or Serum J A M A 120 1262 (Dec 19) 1942

¹ Lourie E M and Yorke Warrington Studies in Chemotherapy—The Trypanocidal Action of Certain Aromatic Diamidines Ann Trop Med 23 289 (Dec 30) 1939

² Thrower W R and Valentine F C O Propamidine in Chronic Wound Sepsis Lancet 1 133 (Jan 30) 1943

³ McIndoe A H and Tilley A R Propamidine in Chronic Streptococcal Infection of Raw Surfaces Lancet 1 136 (Jan 30) 1943

in a water soluble jelly base controlled the infection within four to ten days. Cases with persistent streptococcal infection in wounds constitute a constant danger in an open ward from the point of view of cross infection. Elimination of the responsible organism, therefore, is of the highest importance. The new drug seems to offer the possibility of eliminating this danger and should therefore be useful in a plastic unit.

Morley and Bentley⁴ report encouraging results with propamidine in a small number of cases of burns. They suggest that the drug applied as 0.1 per cent propamidine with 1 per cent amyllocaine hydrochloride in a Mumford base (a Linette wax) may prove an ideal first aid preparation in burns. Almost all their cases have shown on culture a profuse growth of *Proteus vulgaris* and *Pseudomonas aeruginosa* and diphtheroids. These growths have been so profuse that they may have obscured any streptococci and any other organisms present. However, absence of systemic reaction and speedy healing of the burned areas without relapse suggest that streptococcal and staphylococcal infection is effectively controlled. Before grafting is to be contemplated it is necessary, after a period of treatment with propamidine, to eradicate *Proteus vulgaris* and *Pseudomonas aeruginosa*, which are both pus producers.

Kohn Hall and Cross⁵ treated 8 cases of infected wounds and found that Thiersch and pedicle grafting was made possible much earlier with the use of propamidine than with any other method they had used before.

The investigations here summarized seem to indicate that the therapeutic armamentarium against infected wounds is now extended by a product with some virtues not evident in the sulfonamides. Obviously more extended studies are needed to determine under well controlled conditions its relative advantages and limitations. Sulfonamides, penicillin, gramicidin and now propamidine constitute a remarkable list of products useful against infection.

NEW YORK PRESCRIBES STANDARDS TO SAFEGUARD USE OF HUMAN BLOOD PRODUCTS FOR TRANSFUSION

Requirements have been prescribed by the Public Health Council of the State of New York, effective March 1, governing the methods of preparation, distribution and use of human whole blood, human plasma, human serum and other human blood derivatives for transfusion purposes. These requirements, having the effect of law in all areas of the state except New York City, represent, it is believed, the first regulatory action taken by a state body in a field that is growing rapidly in importance not only in relation to war needs but to

civilian emergencies as well. In the Boston night club disaster 1,000 units of plasma was used, representing 300,000 cc of human blood.

The new regulations provide that all laboratory tests required as an aid in determining that blood donors are free from communicable disease, including malaria and syphilis and tests for sterility required to determine that the blood plasma, serum or any derivative is suitable for purposes of transfusion must be made in an approved laboratory. Blood processing laboratories and hospitals must submit to the commissioner of health statements of processing procedures and must keep accurate and complete records. A circular giving detailed instructions for the use of the product must accompany each final container, copies of which are required to be filed with the state health commissioner. Each package must be labeled with the dosage unit value in standard units and the expiration date. Premises, equipment, procedures, records and circulars of instruction must be open to inspection by the state commissioner of health or his authorized representative.

Complete and accurate records must be kept of transfusions by the institutions in which they are performed, the details of which all set up in the new regulations vary according to the substance used, whether human blood, human plasma, human serum or other derivatives. If unstored human blood is used for instance, certification from a physician licensed in New York must be recorded showing that a physical examination of the donor was made within the preceding thirty days, that the donor is free from communicable disease, including malaria and upper respiratory infection, and that the blood of the donor has a hemoglobin content of at least 11 Gm per hundred cubic centimeters of blood. The results of serologic tests for syphilis and of tests to determine the blood group to which both the recipient and the donor belong must be recorded. If human blood plasma, human serum or other derivatives are used for transfusion the records must show the kind of product used, the name and address of the producing laboratory or hospital, the specimen or lot number or other identification of the product and its expiration date.

These new requirements were prescribed after careful and deliberate study by the New York Public Health Council and after a critical review by representatives of several hospitals, the National Institute of Health, the Office of Civilian Defense, the Medical Society of the State of New York and other interested agencies. They follow realization of the possible dangers incident to the use of improperly prepared or stored human blood products for transfusion. This mutual effort by a state agency to safeguard a procedure that may be vital in the preservation of human life is commendable.

Current Comment

SELECTIVE SERVICE PHYSICAL EXAMINATIONS

From the Selective Service System, March 1, has come a new circular to guide physicians and dentists in the preliminary physical examination of registrants. Most of this circular appears under the heading of *Medicine and the War* in this issue of *THE JOURNAL*. The character of the Selective Service physical examination was changed from a complete medical examination to a preliminary "streamlined" physical examination to hasten the actions of the local boards and to compensate to some extent for the shortage of physicians. Moreover, final authority for physical examination rests with the armed forces, it has seemed undesirable to submit the selectee to two complete duplicate physical examinations. The circular emphasizes that an actual inspection of the selectee must be made. Unfortunately some local draft boards have not even examined men in the nude or in action so that boys with only one leg, with draining fistulas or with severe deformities of the spine were sent to induction stations. When the requirements for teeth were changed, some local examiners neglected to inspect the mouth of the selectee. The circular points out that inspection of the oral cavity is still an integral part of the examination and severe dental defects should be sufficient to disqualify the registrant for military service. Finally, the circular emphasizes that the examination must be given by a physician and cannot be delegated to any one less qualified. The details of the examination, as published elsewhere in this issue, should be most carefully studied by every physician whether or not now associated with the Selective Service System. Future developments may require his participation, in some instances he may be called for advice either by the selectee or by others concerned with the decisions of the local board.

CURRENT MORTALITY ANALYSIS

The increased importance at this time of information on public health conditions stimulated the Bureau of the Census to revise its procedure. Certain statistics of national mortality are made available many months in advance of the time formerly possible. This information will be published under the heading "Current Mortality Analysis" and will appear each month approximately seven weeks after the close of the month in which the deaths occur. The first issue, which is concerned with the mortality analysis during the fall months of 1942, has just appeared. During the autumn and early winter of 1942, this report states, surprisingly good health conditions prevailed in the United States. "Current Mortality Analysis" is especially designed for a limited distribution among persons whose work demands that they observe public health trends in the United States during the war. Those making request to the Bureau of the Census may receive this publication without cost.

BULK ETHER

THE JOURNAL and the Council on Pharmacy and Chemistry have commented previously on the use of bulk ether.¹ These are times when restrictions and savings have a special significance. The use of bulk ether may be a contribution to conservation in the war effort. The U S Pharmacopeia XII states that "ether to be used for anesthesia must be preserved in tight containers of not more than 3 Kg capacity." Therefore it would be illegal to ship ether labeled For Anesthesia in containers which hold more than this amount. The Food and Drug Administration feels that the caution statement in U S P XII is applicable to such ether as is "to be used for anesthesia, not to all ether. Accordingly, all ether intended for anesthesia is to be packed in containers of not greater capacity than 3 Kg, all other ether also is required to be packaged in such containers except that it may be shipped in bulk from manufacturers or wholesale distributors when intended for manufacturing or for subsequent repackaging by the dispenser or retail distributor." Under the circumstances, manufacturers or distributors of ether shipped in bulk for purposes other than anesthesia may avoid possible misunderstanding by labeling such ether "Ether Not for Anesthesia" or, if desired, "Ether U S P Not for Anesthesia." U S P XII ether may therefore be shipped in any size container provided it is appropriately labeled.

COLOR BLINDNESS

Newspaper publicity given recently to an alleged cure for color blindness seems to emanate from one J H Lepper, optometrist, of Mason City, Iowa. In reply to inquiries concerning his procedure for correcting color blindness, a form letter is sent in which it is stated "YES, YOUR CASE OF COLOR BLINDNESS CAN BE CORRECTED IF WE DO NOT, IT WILL BE THE FIRST CASE." The statement also suggests that cases take from two to three weeks for correction. If the patient comes to Mason City, \$5 a day is charged. If the prospect finds it impossible to come to Mason City, Lepper says he can send the same equipment, involving two pairs of special colored glasses and one color vision test book, for a total of \$25. A lamp with a reflector and a 60 watt bulb and a flasher if obtainable are also required for home treatment. The form letter is accompanied by a list of testimonials, none of them signed by the writer's full name. Color blindness is a congenital defect. Despite unsubstantiated claims to the contrary, methods of correcting this condition are unknown. Many letters sent to the headquarters of the American Medical Association indicate that men who have had difficulty in gaining entrance to the navy or the air force have been given false hopes by this wholly unwarranted publicity for an unestablished procedure.

MEDICINE AND THE WAR

In this section of The Journal each week will appear official notices by the Committee on War Participation of the American Medical Association, announcements by the Surgeon Generals of the Army, Navy and Public Health Service, and other governmental agencies dealing with medicine and the war and such other information and announcements as will be useful to the medical profession

SELECTIVE SERVICE SYSTEM

GUIDE TO PHYSICAL EXAMINATION OF REGISTRANTS (MEDICAL CIRCULAR NO 3)

March 1, 1943

The purpose of this circular is to guide physicians and dentists in the preliminary physical examination of registrants to the end that all selectees will be physically examined and processed locally in like manner. The following pages furnish the reasons for the adoption of the present system of examination by Selective Service, the instructions covering the preliminary physical examination, section 623.33 (revised) of the regulations, and revised List of Defects (DSS Form 220). It is hoped that each examining physician and dentist will study carefully his personal copy of the circular—familiarize himself thoroughly with the details of the examination, as well as with the lists, and then adhere rigidly to the regulations. The objective is to disqualify all registrants locally who have manifestly disqualifying defects and forward all qualified registrants to the examining and induction station.

This Medical Circular No. 3 affords the welcomed opportunity to express to the examining physicians and dentists of the Selective Service System the appreciation of this headquarters for their loyal and valuable professional service which has proved of the utmost importance in helping the nation to meet its wartime needs.

LEWIS B. HERSHEY, Director

MEDICAL CIRCULAR NO. 3
PRELIMINARY
PHYSICAL EXAMINATION

NATIONAL HEADQUARTERS
SELECTIVE SERVICE SYSTEM

WASHINGTON, D. C.
FEB 15, 1943

The purpose of the Selective Service physical examination of registrants is to dispose of locally and classify into IV-F all registrants manifestly unfit for military service, thereby saving the time of such unfit registrants, the expense incident to travel and the time of the physicians and dentists at the joint induction stations.

The character of the Selective Service physical examination was changed from a complete medical examination to a preliminary physical examination because of the great increase in manpower needed by the armed forces, because of accruing shortage of physicians, and because final authority for physical examination is vested with the armed forces. Now additional demands are being placed on local boards and examining physicians through the discontinuance of recruitment. Executive Order No. 9279, dated Dec. 5, 1942, and LBM No. 178 route through Selective Service channels all men between 18 and 38 years of age who enter the armed forces.

It seems timely to call attention to the present regulations dealing with the character of the examination and to the occasional mistakes on the part of the local board examining physi-

cians which have been due largely to failure to adhere strictly to the regulations. In some instances registrants have been forwarded to recruiting and induction stations with only one leg, with a draining urinary fistula or with deformities of advanced Pott's disease.

Several of these cases were photographed and the pictures forwarded to the War Department constituting incontrovertible evidence that Selective Service Regulations were not followed in these instances and that the registrants had not been examined in the nude and in action. The preliminary physical examination will not be effective unless the registrant is examined in the nude (stripped of all clothing) as prescribed and unless the regulations which apply to the physical examination are rigidly followed (sec. 623.33).

Inspection of the oral cavity is still an integral part of the physical examination. Its purpose is to disclose dental defects which would manifestly disqualify a registrant for military or naval service, as specified in DSS Form 220. As a matter of clinical and statistical interest as to whether or not the registrant is acceptable, the examining physician or dentist should record any unusual anomalies or any pathologic lesions observed during the examination.

The preliminary physical examination as outlined in the Selective Service Regulations should be given only by a physician. Unfortunately, some have erroneously contended that because it consists solely of inspection this examination may be given just as effectively by a lay member of the local board and that it does not call for the professional judgment of a physician. This attitude, no doubt, is partially responsible for the mistakes that have been committed. However, it should be obvious that only a physician is capable of understanding the medical terminology involved in DSS Form 220, that only a physician can supply the professional judgment called for in DSS Form 220, and that only a physician, through a careful and rigid inspection, is capable of determining the existence of many of the physical defects, deficiencies, disorders and diseases listed in DSS Form 220.

The very adoption of this preliminary physical examination reflects the great confidence of Selective Service in its examining physicians. Enthusiastic acceptance by the examining physicians is essential to the success of this program—enthusiasm such as is reflected in the following excerpt from a letter of one of our Selective Service examining physicians who writes the following:

"Many of the examining physicians who are members of my Board of Examining Physicians and who have in their practice of modern, streamlined medicine allowed the inspection phase of physical examination to be supplanted by the X-ray and other laboratory diagnostic measures are beginning to develop their skill of diagnosing defects by an ever improving inspection ability. My examining physicians participating in this present screening type of physical examination have become enthusiastic in playing the game of 'spotting pathology.' Examining physicians who are really interested in this type of examination owe a debt for the privilege of participating in this refresher course which is making them more alert and is developing their senses of sight, hearing and touch in the detection of physical defects."

To meet the present needs Selective Service has revised the regulations pertaining to this preliminary physical examination and the List of Defects. In addition, Selective Service has listed in DSS Form 220 those defects, deficiencies, disorders and diseases which, though not manifest in character, do nevertheless disqualify registrants if properly certified by affidavit filed as prescribed in section 623.33 of the Selective Service Regulations. However the character of the physical examination remains unchanged.

The three requisites to complete success of this preliminary physical examination are:

1. Enthusiastic acceptance of the program
2. Thorough familiarity with the revised regulations section 623.33 and with the revised List of Defects (DSS form 220)
3. Strict adherence to the regulations

Section 623.33—Selective Service Regulations

Physical examination by examining physician—(a) The director of Selective Service from time to time, will issue a list of defects (form 220) which will set forth defects which manifestly disqualify the registrant for military service.

(b) A registrant shall personally appear before the examining physician and shall be examined in the manner provided in paragraph c of this section except when the examining physician or the local board is convinced that the appearance of the registrant for physical examination before the examining physician will be injurious to the registrant's health or the health of those who might be brought in contact with him. When the registrant appears before the examining physician his physical examination should be held in a well lighted, well heated place. It should be held while the registrant is in the nude.

(c) The physical examination should consist of observing the registrant while walking toward, standing before and walking away from the examining physician. The registrant may be required to go through calisthenics to determine the mobility of joints or to furnish a basis for determination of his alertness, intelligence, understanding of commands, postural tensions, tendencies to incoordination and tremors. If peculiarities are noted, simple questions should be asked in an effort to bring out replies bearing on the mental health and personality characteristics of the registrant. The examining dentist or if he is not available, the examining physician will examine the mouth of the registrant. The examining physician will take blood from the registrant for a serologic test. The blood specimen will be collected in a container furnished by the state health officer and will be forwarded to the state laboratory or other laboratory designated by the state director of Selective Service, together with the accomplished form prescribed within the state for such purpose. If the report on the first serologic test of the registrant is other than truly negative the examining physician shall take additional blood for further serologic tests until he is satisfied that the blood is truly negative, truly doubtful or truly positive. Additional blood for further serologic tests will not be taken if distance or circumstances over which the local board or the registrant has no control make it impracticable for additional tests to be taken. Serologic tests will be accomplished without expense to the Selective Service System, unless such expense is specifically authorized by the director of Selective Service. No other laboratory procedures will be undertaken as a part of this physical examination.

(d) Local boards, with the assistance of the examining physician and such agencies as may be designated by the state director of Selective Service, should seek from any source possible information bearing on a history of mental disease in the family of the registrant or social maladjustment, poor work record, other mental or personality disorders of the registrant or any physical condition which might cause the armed forces ultimately to reject the registrant. This information may be secured from local social agencies, school systems, state hospitals, training schools for defectives and any other sources. The local board shall submit lists of registrants whose physical

qualifications are being considered to such agencies as the director of Selective Service or state director of Selective Service may specify to assist in securing this information. The examining physician shall review the information thus received, and the local board shall forward this information or an abstract thereof to the induction station in accordance with arrangements mutually agreeable to the state director of Selective Service and the induction station for the transmittal of such information. When such information is being forwarded, a notation to that effect will be entered under "Remarks" item 25 of the Report of Physical Examination and Induction (form 221).

(e) The examining physician may report to the local board that a registrant is suffering from a condition listed in the List of Defects (form 220) basing his report on one or more of the following: (1) the physical examination of the registrant while he is before him; (2) his personal professional knowledge of the registrant's physical condition; (3) an acceptable affidavit from a reputable physician to the effect that such physician has personal professional knowledge of the registrant's physical condition provided such affidavit is filed with the local board; or (4) an official statement from a government or state agency concerning the physical condition of the registrant (including a statement concerning a registrant who has been cared for in St. Elizabeths Hospital, Washington, D. C. or in a Veterans Administration facility), provided such statement is filed with the local board.

(f) The examining physician shall procure from the registrant the necessary information and shall complete items 22 and 23 of the Report of Physical Examination and Induction (form 221).

(g) The examining physician shall enter in item 24 on the Report of Physical Examination and Induction (form 221) the result of the serologic tests as "Truly Negative," "Truly Doubtful" or "Truly Positive."

(h) The examining physician will enter in item 25 on the Report of Physical Examination and Induction (form 221) any pertinent remarks which he deems advisable for the benefit of the examiners at the induction station.

(i) The examining physician in item 26 on the Report of Physical Examination and Induction (form 221), shall complete the answer to the following question:

Do you find that the above named registrant has any of the defects set forth in the List of Defects (form 220)?

If the examining physician's answer is "Yes," he shall describe the defects in order of their significance. If the examining physician entertains a doubt as to whether he should answer "Yes" or "No," his answer shall be "No." No other information should be included under item 26.

NATIONAL HEADQUARTERS
SELECTIVE SERVICE SYSTEM,
WASHINGTON, D. C.
Jan. 16, 1943

List of Defects

Registrants having any of the following physical defects are disqualified for service in any branch of the armed forces and shall be classified in class IV-F.

ALPHABETICAL LIST

Abscess of the lung
 Achondroplasia
 Acromegaly or gigantism if markedly disfiguring or if associated with other symptoms of severe pituitary dysfunction
 Actinomycosis
 Acute rheumatic fever
 Adhesions of the lids to each other or to the eyeball
 Albino
 Amputation of an arm or leg or complete or partial loss of a hand or a foot
 Amputation of the penis if the resulting stump is insufficient to permit normal function of micturition
 Anus fistula of
 Anus paralysis of the sphincter of
 Aphomia
 Alopecia universalis
 Arch transverse of foot obliteration of associated with permanent flexion of the small toes (claw toes) or with symptom

- Arm amputation of
- Arthritis chronic with deformity disabling or with symptoms
- Asthma chronic
- Atresia of one or both external auditory canals
- Atrophic rhinitis chronic with offensive odor (ozena)
- Atrophies and dystrophies muscular, which are obviously disqualifying
- Auditory canals external atresia of one or both
- Blindness total
- Bone diseases or deformities of which seriously interfere with the weight bearing function with the full use of the limbs or which would prevent the performance of full duty as members of the armed forces
- Bone tuberculosis of
- Brain disease of
- Breathlessness in circulatory failure
- Bronchitis chronic with emphysema
- DSS Form 220 (Revised 1 16 43)
- Canals auditory external atresia of one or both
- Carcinoma or other malignant disease of any organ or part of the body
- Cardiovascular syphilis
- Cerebrospinal syphilis
- Chest wall tuberculosis of
- Chronic pemphigus
- Circulatory failure evidenced by definite symptoms such as a combination of breathlessness cyanosis and edema
- Cleft palate with or without prosthetic appliance
- Cleftfoot if marked in degree or which interferes with the wearing of a military shoe
- Coloboma of iris severe
- Contraction of muscle or paralysis which disturbs function to the degree of interference with service
- Contraction spastic of the neck if sufficient to prevent free rotation
- Cornea ulcer of
- Cretinism
- Curvature of spine if greater than 3 inches in lateral deviation or kyphosis or lordosis severe enough to prevent wearing of equipment or uniform
- Cyanosis in circulatory failure
- Deafness total
- Deformities congenital or due to fracture injury or disease which seriously interfere with function and weight bearing power
- Deformities of the nose throat and mouth which interfere with the mastication of ordinary food with speech or with breathing or that create an unsightly condition
- Deformities postural associated with disease of the sacroiliac and lumbosacral joints obviously associated with muscular spasm and limitation of motion in the lumbar region of the spine and if malingering is definitely excluded
- Dermatitis herpetiformis
- Dilatation of heart and hypertrophy evidenced by displacement of the apex impulse to the left of the midclavicular line or below the sixth rib
- Disease malignant of any organ or part of the body
- Dislocations old unreduced
- Dwarfism
- Dystrophies and atrophies muscular, which are obviously disqualifying
- Edema in circulatory failure
- Elephantiasis
- Emphysema
- Empyema
- Enlargement of thyroid from any cause associated with toxic symptoms or not associated with toxic symptoms but of sufficient size to interfere with wearing of uniform or equipment
- Epidermolysis bullosa
- Epilepsy
- Epididymitis if of a degree to interfere with normal micturition
- Esophagus destructive lesions of
- Exophthalmic goiter
- Exostoses of skull large which will prevent the individual from wearing headgear of any branch of the armed forces
- Extremity loss of
- F eyelid or eyelids conditions of such as inversion or eversion of such degree that forcible closure fails to cover the eyeball or in which there is a resultant conjunctival inflammation corneal irritation or a restriction of the rotation of the eyeball
- Eyes abnormal conditions of due to disease of the brain
- Eyes disfiguring scars of
- Feces incontinence of
- Fingers loss of more than three entire fingers of one hand
- Fistula urinary abdominal osseous or postoperative
- Fistula of the anus
- Flat feet if accompanied by marked symptoms and deformity
- Foot complete or partial loss of
- Fractures of the vertebrae or pelvic bones with associated disqualifying rigidity
- Fractures ununited
- Frohlich's syndrome if severe
- Fungoides mycosis
- Gigantism or acromegaly if markedly disfiguring or if associated with other symptoms of severe pituitary dysfunction
- Glaucoma
- Goiter exophthalmic
- Goiter nontoxic but of sufficient size to interfere with wearing of uniform or equipment
- Hallux valgus (displacement of great toe toward the other toes) if severe and associated with marked exostosis or bunion especially when there are signs of irritation above the joint
- Hand complete or partial loss of
- Heart dilatation or hypertrophy of evidenced by displacement of the apex impulse to the left of the midclavicular line or below the sixth rib
- Hemiplegia
- Hemorrhoids external or internal associated with prolapse of the rectum
- Hermaphroditism
- Hernia complete operable or inoperable
- Hernia of the brain
- Hip diseases of which seriously interfere with function and weight bearing power
- Hodgkin's disease
- Hydrocephalus or monstrosity of the head
- Hypertrophy and dilatation of the heart evidenced by displacement of the apex impulse to the left of the midclavicular line or below the sixth rib
- Hypospadias when opening is proximal to coronal sulcus
- Hysterical paralysis
- Idiocy
- Imbecility
- Immaturity as manifested by infantilism or failure of development of secondary sex characteristics Recheck in six months
- Impetigo chronic
- Incontinence feces or urine
- Insanity with commitment or history of commitment or with authentic medical history of treatment for insanity without commitment
- Jaundice in a degree and kind beyond any question of doubt Recheck in six months
- Jaws diseases of and of associated structures which are likely to incapacitate the individual for satisfactory performance of duty Extensive loss of oral tissue in an amount that would prevent replacement of missing teeth by a satisfactory denture
- Joint tuberculosis of
- Keratitis
- Knee diseases of which interfere with function and weight bearing power
- Kyphosis of a degree sufficient to prevent wearing of uniform and equipment
- Lagophthalmos if associated with signs of hyperthyroidism
- Laryngeal paralysis due to any cause
- Larynx destructive lesions of
- Leg amputation of
- Leprosy
- Leukemia of any type
- Lordosis if of sufficient degree to prevent wearing of uniform or equipment
- Lumbosacral and sacroiliac joints disease of obviously associated with muscular spasm postural deformities or limitation of motion in the lumbar region of the spine and if malingering is definitely excluded
- Lung abscess of
- Lungs tuberculosis of active or authentic history of treatment for within preceding five years
- Lupus vulgaris
- Lymph nodes enlargement of in leukemia or Hodgkin's disease
- Lymph nodes tuberculous
- Lymphosarcoma
- Malignant disease of any organ or part of the body
- Metallic poisoning chronic except argyria
- Monstrosity of the head or hydrocephalus
- Mouth destructive lesions of
- Mouth gross abnormalities which interfere with mastication of food with speech or with breathing or create an unsightly condition
- Multiple sclerosis
- Muscle contraction or paralysis of which disturbs functions to the degree of interference with service in the armed forces
- Muscular atrophies and dystrophies which are obviously disqualifying
- Muscular spasm associated with disease of the sacroiliac and lumbosacral joints obviously associated with postural deformities or limitation of motion in the lumbar region of the spine and if malingering is definitely excluded
- Mutism
- Mycosis fungoides
- Myxedema
- Neck enlargement of lymph nodes of in leukemia or Hodgkin's disease
- Neck spastic contraction of the muscles of if sufficient to prevent free rotation
- Nephritis acute or chronic
- Nose destructive lesions of
- Nose deformities of which interfere with mastication of ordinary food with speech or with breathing or which create an unsightly condition
- Orbit any tumor of
- Osteoarthritis complete or partial of the spinal column
- Osteomyelitis active of any bone or a substantiated history of osteomyelitis of any of the long bones within the past five years
- Overweight excessive which is greatly out of proportion to the height if sufficient to interfere with normal activity or with proper training
- Ozena chronic atrophic rhinitis with offensive odor
- Paget's disease (osteitis deformans)
- Palate cleft with or without prosthetic appliance

- Paralysis hysterical
Paralysis laryngeal due to any cause
Paralysis or contraction of muscle which disturbs function to the degree of interference with duty
Paralysis sphincter of the anus
Paraplegia
Parkinsonian syndrome marked
Pellagra
Pelvic bones healed fractures of with associated disqualifying rigidity
Pemphigus chronic
Penis amputation of if the resulting stump is insufficient to permit normal function of micturition
Peripheral vascular diseases with manifest pathologic changes
Pes planus if accompanied by marked symptoms and deformity
Poisoning metallic chronic except argyria
Postural deformities accompanying disease of the sacroiliac and lumbosacral joints obviously associated with muscular spasm and limitation of motion in the lumbar region of the spine and if malingering is definitely excluded
Prolapse of the rectum
Ptosis of eyelids interfering with vision
Purpura
Rectum prolapse of
Rheumatic fever acute or chronic or history of recurrent attacks
Rhinitis atrophic chronic with offensive odor (ozena)
Ribs tuberculosis of and other parts of the chest wall
Sacroiliac and lumbosacral joints disease of obviously associated with muscular spasm postural deformities or limitations of motion in the lumbar region of the spine and if malingering is definitely excluded
Scars adherent of skin or soft tissue of a degree which seriously interfere with function
Scars disfiguring to such an extent as to be unsightly or which interfere with function of a limb or part to such a degree as to prevent satisfactory performance of service in the armed forces
Sclerosis multiple
Sinus of the abdominal or chest wall
Skin adherent scars of or soft tissues to a degree which seriously interfere with function
Skin chronic ulcers of, if severe in degree or associated with varicose veins
Skull deformities of of any degree associated with evidences of diseases of the brain spinal cord or peripheral nerves
Skull depression of of a serious degree
Skull exostoses large which will prevent the individual from wearing headgear of any branch of the armed forces
Spasm muscular with disease of the sacroiliac and lumbosacral joints obviously associated with postural deformities or limitation of motion in the lumbar region of the spine and if malingering is definitely excluded
Sphincter of the anus or urethra paralysis of
Spinal column osteoarthritis of partial or complete
Spine curvature of if greater than 3 inches in lateral deviation
Kyphosis or lordosis severe enough to prevent wearing of uniform or equipment
Spleen great enlargement of from any cause
Spondylitis disabling or deforming
Stammering or stuttering to such a degree that the registrant is unable to express himself clearly or to repeat commands
Strabismus permanent or well marked
Syphilis cerebrospinal cardiovascular visceral
Sycoosis (barbers' itch or other types) Reconsider after recovery
Throat destructive lesions of
Throat gross abnormalities of which interfere with mastication of food with speech or with breathing or create an unsightly condition
Thumbs loss of both
Thyroid enlargement from any cause associated with toxic symptoms or not associated with toxic symptoms but of sufficient size to interfere with wearing of uniform or equipment
Total deafness
Tracheostomy
Trachoma
Transverse arch of foot obliteration of associated with permanent flexion of the small toes (claw toes) or with symptoms
Tuberculosis active of any part of the body
Tuberculosis healed of any portion of the vertebral column
Tumor of brain
Tumor of orbit
Ulcer of cornea
Ulcers chronic of skin if severe in degree or if associated with varicose veins
Urinary fistula
Varicose veins, if severe in degree or associated with edema or with present or previous ulcer of the skin
Vascular diseases peripheral with manifest pathologic changes
Veins varicose if severe or associated with edema or with present or previous ulcer of the skin
Vertebrae healed fractures of with associated disqualifying rigidity or deformity
Vertebral column tuberculosis of any portion healed
Visceral syphilis of
Weight excessive overweight which is greatly out of proportion to height if sufficient to interfere with normal physical activity or with proper training
Xerophthalmia

Conditions which may not be manifest but which may be certified as disqualifying a registrant for service in any branch of the armed forces and classified as IV-F, when they are known to the examining physician in accordance with section 623.33(c), as amended, of the regulations

- Acute diseases other than venereal Reconsider after recovery
Addison's disease
Alcoholism, chronic to such a degree that it interferes with earning a living in civil life
Anemia pernicious necessitating the constant parenteral administration of liver extract
Diabetes insipidus moderate or severe
Diabetes mellitus if severe or if necessitating the constant administration of insulin
Drug addiction
Enuresis continuous from childhood
Epilepsy
Hypoglycemia chronic persistent to such a degree that it interferes with earning a living in civil life
Insanity with commitment or history of commitment or with authentic medical history of treatment for insanity without commitment
Nephritis acute or chronic
Peptic ulcer active confirmed by x-ray examination
Rheumatic fever acute or chronic or with history of recurrent attacks
Sex perversion
Tuberculosis of any part active within five years

TREATMENT OF FRACTURES OF HANDS AND FINGERS CAUSED BY GUNSHOT WOUNDS

V. GUSYNIN

Professor, Chair of Neurosurgery at Lenin Postgraduate Medical College of Kazan and Consultant, Military Hospital of Tartar Soviet Republic

(The following article was received by cable from the Soviet Scientists' Antifascist Committee.—Ed.)

Fractures of hands and fingers caused by gunshot wounds are frequent war injuries. The correct treatment is fixation and stretching the fingers over a solid cylindric body. This gives the fingers the physiologic half contracted position. Fixation on a cylindric splint should be centralized on the fractured bone and pressure exerted on the point of fracture. This pressure prevents the bone fragments from moving so that they heal and remain in position. A fixing bandage is applied with turns of the bandage crossing behind the broken bone at the point of fracture. The bandage passes between the fingers according to the position of the fracture in the direction of the wrist, around which transverse turns are made in both directions. The usual wide absorbent bandage is applied over the sterilized fixing

bandage and is changed whenever it becomes saturated. The fixing bandage is not changed unless absolutely essential but is occasionally soaked with iodine. Healthy fingers must be left absolutely free.

I have also proposed the use of a so called "drum splint," consisting of a wooden cylinder fixed to the split end of a flat splint. The flat splint is placed on the palm side of the forearm and injured fingers are placed around a cylinder. When necessary, the fingers are stretched by elastic bands fastened to the flat splint in a centripetal direction.

Fixation of fingers in a functionally essential position may also be carried out by use of a simple wooden roller.

In field conditions, a bottle 6 or 7 cm in diameter may be used as a cylindric splint for fingers. The bottle is convenient because it can be used for physiotherapeutic heat treatment, the bottle being filled three or four times a day with warm water.

CIVILIAN DEFENSE

DR BAEHR TO VISIT HAWAII

Dr George Baehr, chief medical officer, Office of Civilian Defense, Washington, D. C., will leave San Francisco shortly for Hawaii. At the invitation of the governor of the territory, Dr Baehr will confer with local authorities on civilian defense activities which are being recognized now that the government of the islands is in the process of being transferred from the Army to civil authorities. He will remain in the islands about two weeks. En route to Hawaii Dr Baehr will confer with Emergency Medical Service officers in California and will speak at the war conference of the California Hospital Association, Berkeley on "Recent Observations in England and Scotland" and "Hospital Participation in the Emergency Medical Service."

EMERGENCY DISTRIBUTION OF BLOOD PLASMA

The Office of Civilian Defense, Washington, D. C., on February 15 issued additional details concerning Circular Medical Series No 27, which is as follows:

1 The U. S. director of civilian defense has made arrangements so that the Civil Air Patrol will fly blood plasma supplies into stricken areas in the event of emergencies.

2 In instances in which, owing to bombing fire tornado or other cause it becomes necessary to supplement stocks of blood plasma in stricken areas, and when other methods of transportation are not available or are inadequate, the regional medical officer of civilian defense should contact the appropriate wing commander of Civil Air Patrol and request emergency air transportation for the plasma. Wing commanders have been authorized to accept such requests only from the regional medical officers.

3 In such event, give the wing commander complete details as to where the plasma is to be picked up and delivered. Arrangements should then be made by the regional medical officer to deliver the plasma to and from the airports.

4 These arrangements will apply for all states except those located within the jurisdiction of the Western Defense Command. In those states it is understood that the Western Defense Command has sufficient nontactical airplanes available to furnish such transportation.

5 Appropriate instructions, which will insure the efficient operation of this transportation facility, will be furnished to state and local chiefs of Emergency Medical Services by their regional medical officers.

6 The current list of wing commanders, Civil Air Patrol, is being furnished to the regional medical officers.

MISCELLANEOUS

PUBLIC HEALTH UNDER HITLER

Nieuwe Rotterdamsche Courant of Dec 2, 1942 gives details of the increasing diphtheria epidemic. There were 12,225 cases in 1942 (there were 1,273 in 1939) and during the last few months there have been twice as many cases as during the first months of the year. There were 1,095 cases in August and 2,156 cases in October, about 250 cases a week in August and 650 a week in October. The greatest increase has been in North Holland, South Holland and Utrecht, and the smallest has been in North Brabant, Gelderland and Limburg, the very provinces where diphtheria has for a long time been prevalent and from which the illness has been spreading all over the country. It has been generally noted that older people have been the most affected by the disease. In 394 of the 1,034 municipalities young people under 14 have been vaccinated this year against diphtheria. The Rijksseruminstituut (National Serum Institute) is working under heavy pressure in order to be able to supply the necessary serum.

Reichs-Gesundheitsblatt, Berlin, of Dec 23, 1942 contains a decree by the minister of the interior ordering the closing down of the Jewish lunatic asylum at Berndorf-Sayn. The Jewish hospital in Iranische Strasse, Berlin, will have a special mental ward which will serve as a substitute for the closed institution.

To insure economy in the use of quinine, the following points for doctors were published in *Reichs-Gesundheitsblatt*, Berlin, Dec 16, 1942. Quinine must not be given as a prophylactic against grip or as a tonic. It is to be replaced by the sulfonamides in the treatment of bronchopneumonia and by aminopyrine in the treatment of general infections, sepsis and typhus, where it has sometimes been used to bring down the temperature. When necessary, it may still be prescribed together with synthetic drugs in the treatment of malaria.

According to *Uj Nemzedek* of Dec 9, 1942, the government asked the alispán of Pest County (Istváó Endre) to set up a temporary isolation hospital equipped with 1,000 beds to counteract the epidemic of influenza, which is on the upgrade. The alispán answered that the means of the county were insufficient to set up a hospital and that for this reason those localities in which a large number of influenza cases occurred must themselves set up temporary hospitals.

The *Swiss Democrat* of January 22 reports that not only Chasso but all the communes in the Canton Ticino all along the Swiss-Italian frontier have adopted strict precautionary measures against the dangers from the typhoid epidemic on the Italian side of the frontier.

According to *Upsala Nya Tidning* of January 5 at least 2,000 "inferior" Norwegians will be sterilized according to a new law.

Universal of January 7 reports that the Ministry of Education ordered medical students to examine all Rumanian school pupils on January 11. Infected pupils will be kept under observation.

ARMY-NAVY PRODUCTION AWARDS

Brig Gen John M. Willis, commanding general at Camp Grant, Ill., presented the Army-Navy E award to the president of Parke, Davis and Company, Dr. A. W. Lescolner, at Detroit February 26. The insignia, an E pin, which every employee is entitled to wear, was presented by Lieut. E. B. Williams, senior medical officer of the Detroit Naval Armory, to Mr. John Tighe, who represented the employees. Dr. Edgar H. Norris, dean of Wayne University College of Medicine, presided. Among the guests were Capt. R. T. Brodhead and Comdr. A. M. Cohan of the Navy, Col. C. F. Shook and Major Roscoe Cavell of the Army Medical Corps, Mayor Edward J. Jeffries of Detroit, Dr. W. D. Barrett, president-elect of the Wayne County Medical Society, Dr. Bruce H. Douglas, health commissioner of Detroit, Dr. W. B. Cooksey, medical director, Detroit Section, the American Red Cross, Albert R. Pisa, president of the Detroit Retail Druggists Association, Dean R. T. Lake of the College of Pharmacy of Wayne University, Dean E. P. Stout, College of Pharmacy, Detroit Institute of Technology, J. H. Webster of the Detroit Board of Education and Warren E. Bow, superintendent of Detroit public schools. Mr. Joseph Roberts and Miss Lillian Payne, who have been employed by Parke, Davis and Company since 1892 and 1896 respectively, were among the honored guests.

Sharp & Dohme, Inc., pioneers in the development of dried plasma and producers in their Philadelphia and Glenolden laboratories of many other medical supplies for the armed forces, were awarded the Army-Navy E for excellence in production on February 10. The E pennant was presented by Brig Gen Hugh Jackson Morgan, chief consultant in medicine, Office of the Surgeon General, U. S. Army, Washington, D. C., and the individual E pins were presented by Commander E. L. Bortz, U. S. N. R., of the Naval Hospital, Philadelphia, to representatives of the employees of the company.

The Army-Navy E Production Award was presented to the men and women employed by the Ciba Pharmaceutical Products, Inc. of Summit, N. J., February 19, for excellence in war production.

ORGANIZATION SECTION

OFFICIAL NOTES

DOCTORS AT WAR

Radio broadcasts of Doctors at War by the American Medical Association in cooperation with the National Broadcasting Company and the Medical Departments of the United States Army and the United States Navy are on the air each Saturday at 5 p m Eastern War Time (4 p m Central War Time, 3 p m Mountain War Time, 2 p m Pacific War Time). An exception is the Chicago area where the broadcasts are heard by transcription at 8 p m Central War Time Saturdays on station WMAQ until March 27, after which they will be heard at 10 30 p m Central War Time. Unless otherwise indicated each program is summarized by Dr W W Bauer, Director, Bureau of Health Education.

The titles and speakers for the next four programs are as follows:

March 27 War Worker Sleeps Here!
April 3 The White Plague 1943
Speaker: Dr Kendall Emerson, managing director, National Tuberculosis Association

April 10 Battle Stations at Home!
Speaker: Col George Brehr, Chief Medical Officer, Office of Civilian Defense
April 17 Stratosphere Flight!
Speaker: Brig Gen David N W Grant, Air Surgeon, United States Army

BEFORE THE DOCTOR COMES

The American Medical Association program on radio station WLS (890 kilocycles) entitled "Before the Doctor Comes" will be on the air every Thursday up to and including May 27 at 9 45 a m. This program is intended to be helpful to the mothers of young children. Dr W W Bauer, Director of the Bureau of Health Education, will be interviewed by Mrs June Merrill on common home health problems. The titles for the next four programs are as follows:

March 25 The Child with Tummy Ache
April 1 The Child with Ear Ache
April 8 What To Do About Cuts and Scratches!
April 15 What To Do About Bad Bumps

MEDICAL LEGISLATION

MEDICAL BILLS IN CONGRESS

Changes in Status—S 786 has passed the Senate and has been favorably reported to the House, a bill providing for the rehabilitation of disabled veterans of World War II. H R 1749 has passed the House and Senate a bill granting hospitalization, domiciliary care and burial benefits to veterans of World War II. H R 1975 has passed the Senate a bill to provide deficiency appropriations for the fiscal year ending June 30, 1943. The bill retains the provision providing that during the existing war, and for six months thereafter any commissioned officer of the regular corps of the Public Health Service may be appointed to higher temporary grade with the pay and allowances thereof without vacating his permanent appointment and that reserve officers of the Public Health Service may be distributed in the several grades without regard to the proportion which at any time obtains or has obtained among the commissioned officers of such service. The bill appropriates for the use of the Public Health Service an additional amount of \$85,500 for disease and sanitation investigations, and an additional amount of \$428,500 for emergency health and sanitation activities. The limitation on the amount which may be expended for the procurement and establishment of reserves of blood plasma or serum albumin is increased from \$420,000 to \$499,500. The bill was amended in the Senate to authorize an appropriation of \$1,200,000 for the fiscal year 1943, for use by the Children's Bureau in making grants to the states to provide medical, nursing and hospital maternity and infant care for wives and infants of enlisted men in the armed forces of the United States of the fourth, fifth, sixth or seventh grades. S 785 has been reported to the Senate, authorizing an appropriation of \$2,000,000 to provide for the expansion of facilities for hospitalization of dependents of naval and marine corps personnel and for hospitalization, outside of the continental limits of the United States, of officers and employees of any department or agency of the federal government and employees of any contractor with the United States or his subcontractor, and the dependents of such persons and, in emergencies, of such other persons as the Secretary of the Navy may prescribe.

Bills Introduced—The President has submitted to Congress the Report of the National Resources Planning Board, to be made available as H Doc 128. This report, among other things, recommends an extension of the social security program to include permanent and temporary disability insurance, immediate action by the federal government in cooperation with the

medical profession to enable every person to budget medical expenses over a reasonable period, and federal aid in developing an adequate system of regional and local hospitals, maternal and child care and other measures to assure "adequate medical and health care for all, regardless of place of residence or income status." S 762, introduced by Senator Danaher, Connecticut, proposes to amend the Soldiers' and Sailors' Civil Relief Act of 1940 as amended to afford relief in the case of certain leases made by corporations or partnerships. S 838, introduced by Senator LaFollette, Wisconsin, provides for vocational rehabilitation of persons disabled in war industries or otherwise. S 847, introduced by Senator Bilbo, Mississippi, provides for certain payments to needy blind individuals. H R 1826, introduced, by request, by Representative Lesinski, Michigan, provides for presumption of soundness at enlistment after six months active service in the armed forces during the present war. H R 1978 introduced by Representative Maas, Minnesota, directs the director of the Selective Service System to award and cause to be issued to each registrant who has been rejected for active military service or deferred because of physical condition or essential work in the defense industry a suitable lapel button or pin to indicate that the individual is unable to enter the military service through no fault of his own. H R 1981, introduced by Representative Johnson, Indiana, proposes to amend the National Service Life Insurance Act so as to provide benefits for permanent total disability. H R 2100, introduced by Representative Patman, Texas, a bill to mobilize the scientific and technical resources of the nation, and to establish an Office of Scientific and Technical Mobilization. H R 2102, introduced by Representative Abernethy, Mississippi, a bill to exclude from gross income, for purposes of federal income taxes, amounts received as compensation for active service in the military or naval forces of the United States.

STATE MEDICAL LEGISLATION

Arkansas

Bills Introduced—S 363 proposes to authorize the creation, operation and maintenance of county boards of health in counties having a population of 100,000 or over. H 382 proposes that all school teachers, school bus drivers, school cafeteria employees, school janitors and other school employees shall present a certificate of health including skin test for tuberculosis issued by a regularly licensed physician or a regularly

constituted health authority, not longer than three months prior to an application for a position in the school system. Such certificate shall be renewed each three years and the county and city health officers who issue same shall do so free of charge.

Bill Passed—H 432 passed the senate, March 6. It proposes to prohibit the sale of appliances, drugs or medicinal preparations having special utility for the prevention of conception or venereal diseases without a license issued by the state board of pharmacy but would except physicians and medical practitioners regularly licensed to practice medicine or osteopathy.

Bill Enacted—H 103 was approved, March 5. It provides for the appropriation of \$15,000 to purchase pneumothorax equipment and to pay the fees of physicians for administering pneumothorax treatment to patients certified by the superintendents of the tuberculosis sanatoriums.

California

Bill Introduced—S 650, to amend the school code, proposes to authorize the school authorities to grant temporary exemption to pupils attending school during the time such pupils are working in industries, business, or in agricultural pursuits essential to the war effort, and further authorizes the superintendent of public instruction to set minimum health and physical fitness standards which each pupil shall be required to meet before being granted such temporary exemption.

Bill Enacted—A. J. R. 26 has become Resolution Chapter 50 of the Laws of 1943. It resolves that the assembly and senate of the state of California endorse the pharmacy corps bill, S 216 and H. R. 997, and request the Congress to enact the same into law.

Colorado

Bill Introduced—S 333 proposes to authorize the state board of health to declare emergency areas and to authorize all full time state, county and municipal public health officers who are graduates of medical schools approved by the state board of health and who possess licenses to practice their profession from the appropriate licensing authorities of Colorado or any other state to engage in the practice of medicine in Colorado, regardless of whether or not they hold licenses so to do from the licensing authorities thereof, until such time as the state board of health shall declare the emergency at an end. Such health officers shall charge the usual fees for services prevailing in the community and remit them to the state department of revenue.

Connecticut

Bill Introduced—Substitute for H 1073 proposes to authorize a jailer who has under his supervision a person whom he believes to be mentally ill to have such person examined by a reputable physician and, on recommendation of such physician, transferred to a state hospital for mental illness.

Bill Passed—S 261 passed the house, March 4. To amend the premarital examination law, it proposes to permit the required certificate to be signed by a physician licensed to practice medicine in the state of Connecticut or any state or territory of the United States or the District of Columbia.

Delaware

Bill Introduced—House substitute for H 66 proposes the creation of a state board of examiners in optical dispensing, defines optical dispensing as the filling or compounding of physicians' prescriptions for lenses and other optical devices, the surveying and measuring of external features of the face and head for the proper fitting of such lenses, and the fitting of such lenses to the user, and further proposes that the services and appliances relating to optical dispensing shall be dispensed, furnished or supplied to the intended wearer or user thereof only on prescription issued by a physician or an optometrist.

Georgia

Bill Introduced—H 141-194 A proposes a resolution urging the Congress of the United States to give its full and earnest support to the passage of H 997 and S 216, either of which would establish a pharmacy corps in the United States Army.

Idaho

Bill Enacted—S 140 has become chapter 134 of the Laws of 1943. To amend the occupational disease act, it authorizes the industrial board to summon the medical panel to attend hearings and authorizes the members of such panel to question witnesses.

Illinois

Bills Introduced—S 95 proposes the creation of a chiropractic board by the director of registration and education and defines chiropractic as the science of palpating and adjusting the articulations of the human spinal column, correcting interference with nerve transmission and expression to restore health, without the use of drugs or surgery. S 167 proposes the creation of a state board of health to take over the duties of the department of public health.

Bill Passed—S 21 passed the senate, March 10. To amend the traffic laws, it proposes that a person shall be deemed, prima facie, to be operating a motor vehicle under the influence of intoxicating liquor whose blood, urine, saliva or alveolar breath contains more than certain stated percentages of alcohol as determined by a chemical test of such breath or body fluid.

Indiana

Bills Passed—S 4 passed the house, March 4. It proposes the enactment of a law to license and regulate nursing homes. H 66 passed the senate, March 6. It proposes the enactment of a law regulating the operation of plants for the cold storage of food in individual lockers. Among other things the bill proposes that all employees of such locker plants shall undergo a semiannual health examination by a physician and requires the employer to keep such health certificates on file at all times. Furthermore, the bill proposes to prohibit any person suffering from a communicable disease, including any communicable skin disease or with infected wounds, and any person who is a "carrier" of a communicable disease from being employed in any capacity in such locker plant.

Bill Enacted—S 134 has become chapter 222 of the Laws of 1943. It provides regulations for the sanitation of places in which food is made or handled and provides further that no person shall be employed in any such place who is affected with any venereal disease, smallpox, diphtheria, scarlet fever, yellow fever, tuberculosis or consumption, bubonic plague, Asiatic cholera, leprosy, trachoma, typhoid fever, epidemic dysentery, measles, mumps, German measles, whooping cough, chickenpox or any other infectious or contagious disease.

Kansas

Bill Introduced—S 167 proposes an act relating to state boards and commissions. Among other things, it would require the state board of medical examiners to make biennial rather than annual reports to the governor at least ten days prior to each regular session of the legislature and to make typewritten reports to the governor in the odd numbered years. In addition to biennial and annual reports, each state agency covered by the proposed bill may have printed such other reports, pamphlets, books and material as pertain to its activity and which are within the terms of a specific legislative authorization or appropriation.

Bills Passed—H 120 passed the senate, March 6. It proposes to excuse physicians in the military service from renewing their licenses annually and prohibits revocation of such license during such period. H 121 passed the senate, March 6. To amend the medical practice act, it proposes to eliminate the requirement that no two of the required four six month periods which must be spent in the study of medicine and surgery may be given within the same twelve months. The purpose of this bill is to enable graduates of accelerated medical courses to obtain licensure in Kansas. H 325 passed the house, March 5. It proposes to provide for treatment of nonresidents who have been diagnosed as having active tuberculosis.

Nevada

Bill Passed—A 141 passed the assembly, March 5. It proposes to authorize the board of medical examiners to grant qualified physicians a temporary license to practice medicine, surgery or obstetrics in any particularly specified part of the

state for and during the period of time limited by the license. The proposal would further authorize the board of medical examiners, from time to time, to restrict, enlarge or change the territorial limits stated in such temporary license.

New Jersey

Bill Passed—A 93 passed the senate, March 8. It proposes to amend the medical practice act by granting an extension of two years within which a licensee must furnish proof of his actually having become a citizen.

New Mexico

Bills Introduced—H 223 proposes to repeal the existing law relating to the practice of chiropody. H 247, to amend the basic science law, proposes to exempt therefrom persons engaged in the practice of the religious tenets of any church in the ministrations to the sick or suffering by mental or spiritual means. H 252 proposes to require every practitioner of medicine and surgery to register annually and fixes the fee for resident physicians at \$2 and for nonresident physicians at \$10.

New York

Bill Passed—A 1125 passed the assembly, March 8. To amend the medical practice act, it proposes to postpone until July 1, 1944 the 1942 amendment exempting students, interns and resident physicians from the operation of the medical practice act.

North Carolina

Bill Passed—S 254 passed the house, March 6. It proposes the creation of a Hospital Authority to engage in hospital construction, maintenance and operation.

Bills Enacted—H 429 was ratified, March 1. It provides that any person having tuberculosis in a communicable form who fails to follow the instructions given him by an agent of the county board of health as to precautions which he should take shall be imprisoned in the Prison Department of the North Carolina Sanatorium. H 476 was ratified, March 4. It provides that persons serving in the armed forces or merchant marine shall be exempt from liability for any and all license taxes levied by the state or by any county or city in the state for the privilege of engaging in or carrying on any trade or profession in which such person was engaged before entering the service and further provides that such person during the period of service shall be exempt from paying any license fees to any licensing board or commission or to the state of North Carolina in which the payment of such license fee is by law required as a condition to the continuance of the privilege of engaging in any trade or profession. H 513 was ratified, March 4. It authorizes the state board of optometry to make use of the injunctive process in restraining the illegal practice of optometry.

North Dakota

Bills Passed—S 58 passed the house, March 4. It proposes to amend the premarital examination law by authorizing the required laboratory test for syphilis to be performed by the state department of health or by any other state public health laboratory approved by the state health officer. S 77 passed the house, March 4. It proposes to provide for the establishment, maintenance and duties of a district board of health and provides that the district health officer appointed by such board shall be a physician and surgeon regularly licensed to practice medicine and surgery in the state. H 229 passed the senate, March 4. It proposes a law for the organization and regulation of nonprofit hospital service plan corporations.

Ohio

Bills Introduced—H 181, to amend the sales tax law, proposes to exempt therefrom the sales of "patent" and prescription medicines. H 306, to amend the workmen's compensation act, proposes to authorize the furnishing of orthopedic appliances and artificial limbs to injured employees, in addition to any other compensation received.

Bill Passed—S 46 passed the senate, as amended, March 2. To amend the criminal code, it proposes that any person not being lawfully authorized to do so who shall mutilate or destroy any portion of the dead body of any person shall be

guilty of a felony. The existing law already authorizes medical schools to obtain bodies for dissection purposes.

Oklahoma

Bills Introduced—S 98, to authorize the performance of postmortem cesarean sections on the body of a female who is the victim of death and who at the time of accidental death is in the advanced stages of pregnancy with possibilities of viable child was amended in the senate to provide that such operation shall not be performed over the protest of those in whom the law has recognized a legal right to the possession of the body of the deceased. S 144 proposes to require every physician making an examination of a person infected with a venereal disease to have a standard serologic test made of such person's blood. S 253 proposes to provide for the commitment, custody, care and treatment of persons so far addicted to the intemperate use of stimulants as to have lost their power of self control or persons subject to dipsomania or inebriety. H 249 proposes the creation of a special indemnity fund out of which employees would receive compensation for disability resulting because of the employee being a physically impaired person, defined to be a person who has suffered the loss of the sight of one eye, the loss by amputation of some member of his body, or the loss of the use, or partial loss of the use, of a specific member such as is obvious and apparent from observation or examination by an ordinary layman, that is, a person who is not skilled in the medical profession.

Bills Passed—S 98 passed the senate, March 4. It proposes to authorize a physician legally qualified to practice in the state of Oklahoma to perform a postmortem cesarean section when the physician has reason to believe that the child is viable in the mother. In the performance of such operation, the physician shall not be liable either civilly or criminally, provided only that the operation is performed in good faith and with due skill and without unnecessary injury or mutilation. H 37 passed the house, March 1. It proposes that state and local officers, or their authorized deputies who are physicians, be empowered to detain and examine persons suspected of being infected with a venereal disease and authorizes the detention of such persons until the results of an examination are known. The examination must be made by a health officer or, at the option of the person to be examined by an approved licensed physician.

Oregon

Bills Passed—S 284 passed the senate on March 4 and the house on March 5. It proposes to authorize the payment of compensation to employees disabled by an occupational disease. H 229 passed the senate, March 9. It proposes to reenact and extend the existing law providing for state reimbursement to hospitals for services rendered victims of motor vehicle accidents so as to cover nurses and operators of ambulances. A provision also including services rendered by doctors was eliminated by the house. H 103 passed the senate, February 26. To amend the law relating to the examination of handicapped children, it proposes to authorize examinations of the eyes of such children to be made and the findings certified to by qualified and licensed optometrists. H 350 passed the senate, February 26. It proposes to authorize commissioned medical officers of the army to execute the required certificate necessary under the state premarital examination law. H 371 passed the house, February 26. It proposes an appropriation to pay for medical, surgical, corrective and other services and facilities for crippled children or children who are suffering from conditions which lead to crippling.

Bills Enacted—S 175 was approved, March 4. It increases the annual registration fee for physicians from \$5 to \$10 for the period beginning Jan. 1, 1944. H 101 has become chapter 187 of the Laws of 1943. It amends the law relating to cosmetic therapy by proscribing the removal of warts, moles or other blemishes by an electrologist. H 245 has become chapter 178 of the Laws of 1943. It requires persons maintaining a hospital for the treatment of persons with mental disorders or mental defects to obtain a license from the state board of health.

Pennsylvania

Bills Introduced—S 195, to amend the act relating to coroners, proposes that in all counties where a coroner or deputy coroner receives a salary and himself makes an autopsy or postmortem examination authorized to be made by him he shall be entitled, if he is a duly licensed physician or surgeon, to extra compensation from the county for making the same in such amount as the commissioners of the county shall fix. S 244 proposes that for the duration of the war a minimum of nine months shall constitute the necessary training for an intern in a hospital approved for intern training to qualify for admission to an examination for licensure by the osteopathic surgeons' examining board to practice major surgery in Pennsylvania. H 459, to amend the law relating to the practice of optometry, proposes that nothing in such law shall prevent the employment by any person, firm or corporation of a registered optometrist to be in charge of or to practice optometry in an optical department or store owned, controlled or conducted by a corporation. H 504 proposes to exempt physicians in the armed forces or merchant marine from being required to renew their licenses during the term of such service and to authorize such persons to apply for renewal thereof at any time within one year after their discharge. H 540 proposes the creation of a board of chiropractic examiners and defines chiropractic as the science of palpating and adjusting the articulations of the human spinal column. The proposal would further provide that nothing in the act should be construed to prevent any regularly licensed chiropractor, physician or surgeon of the commonwealth who has procured a license to practice chiropractic in accordance with the provisions of the proposal from practicing both medicine, surgery and chiropractic.

Bill Passed—S 103 passed the senate, March 2. It authorizes counties to create a medical clinic, composed of a psychiatrist, a psychologist and such investigators and clerical help as might be needed, which medical clinic shall pass on the mental and physical condition of all persons convicted of all crimes who are first offenders, obviously mental cases convicted of sex offenses or alcoholic or narcotic cases.

South Carolina

Bill Enacted—S 17 has become Governor's Act No 24 of the Laws of 1943. It eliminates from the medical practice act the requirement that the necessary four full courses of lectures of at least twenty-six weeks each must have been given in four different calendar years. The purpose of this law is to enable graduates of accelerated medical courses to obtain licensure in South Carolina.

South Dakota

Bill Passed—S 129 passed the senate on February 26 and the house on March 4. As amended by the senate, it would exempt from the basic science act persons engaged in the practice of hydrotherapy. The original proposal also exempted persons acting as an assistant or under the supervision and direction of one holding a basic science certificate and teachers of physical education as taught in regular grade and high schools of the state.

Bills Enacted—S 186 was approved, March 1. It provides for an appropriation for the purchase and installation of hydrotherapy equipment in the state hospital for the insane. S 202 was approved, March 4. It makes it unlawful to give for use as a beverage any intoxicating liquor to any person under the age of 18 years unless it is done in the immediate presence of a parent or guardian of such minor or by prescription or direction of a duly licensed practitioner or nurse of the healing art for medicinal purposes. H 84 was approved, February 24. It amends the workmen's compensation act by adding necessary first aid treatment to the services to be furnished by an employer. H 206 was approved March 8. It authorizes the sterilization of inmates of the state hospital on recommendation of the superintendent when it is shown that the inmate suffers from certain mental diseases perversion or diseases of a syphilitic nature and that the person is capable of procreation. The law also makes provision for the voluntary sterilization of any inmate.

Texas

Bills Introduced—H 529 proposes the creation of a state board of examination and registration for physicians and surgeons of the osteopathic school of medicine. Osteopathy is not defined, but the proposal would provide that each applicant who successfully passes the required examination shall be issued a license to practice as a physician and surgeon of the osteopathic school of medicine according to the provisions of the act and further provides that each license would give the holder thereof the unlimited right to practice medicine and surgery. It is further proposed that physicians and surgeons of the osteopathic school of medicine should have the same rights, privileges and immunities and stand charged with the same public duties and obligations as the duly licensed physicians and surgeons of any other school of medicine. Licensates should observe and be amenable to all state and municipal laws, rules and regulations pertaining to reporting births and deaths and all matters pertaining to public health, public sanitation, the control of infectious diseases, the compilation of vital statistics, health insurance, workmen's compensation, care of the indigent, and care of mothers and infants, with the same rights thereunder as duly licensed physicians and surgeons of any school of medicine and reports of licensates would be accepted by the officers of the state and municipal departments to which the same are made. Each licensate would have the same rights with respect to the treatment of individuals and cases, the same right to register under the laws of the United States governing narcotics, the same right to hold public office and public employment and the same right to practice in state county and municipal hospitals as is conferred by any license that may be issued to any other licensee of any other school of medicine. Duly licensed physicians and surgeons of the osteopathic school of medicine and the duly licensed physicians and surgeons of other schools of medicine would be accorded equal and uniform privileges and opportunities in all state county and municipal hospitals and in all institutions supported maintained or operated in whole or in part by the state of Texas or any political subdivision thereof for the treatment of human disease, infirmity or ailment and in all hospitals which are tax exempt by reason of their charitable nature. H 540 proposes to repeal the existing medical practice act and to enact a new medical practice act amending the existing law by, among other things, excluding therefrom licensed osteopaths and chiropractors who confine their practice strictly according to the definition thereof which may in the future be authorized by law, decreasing the personnel of the state board of medical examiners from twelve to six members requiring licensates to present a certificate from the board of examiners in the basic sciences and repealing the provision requiring annual registration of licenses. H 591 proposes to change the method of applying for admission to the state tuberculosis sanatorium.

Bill Passed—H 20 passed the house, March 4. It proposes the creation of a separate state board of examiners for chiropractors and defines chiropractic to be the science of palpating and adjusting the articulations of the human spinal column and its connecting tissues without the use of drugs or surgery.

Utah

Bills Introduced—S 202 proposes the enactment of what appears to be the uniform narcotic drug act. S 203 to amend the law relating to narcotic drugs, proposes to exempt therefrom the sale and administration of certain attenuated narcotic preparations.

Bill Enacted—House concurrent memorial No 1 was adopted February 26. It resolves that the legislature of Utah endorse and recommend to the Congress of the United States the enactment of H R 997 or S 216, either of which would establish a pharmacy corps in the regular army.

Vermont

Bills Introduced—H 88 proposes that any person who has sexual intercourse while infected with gonorrhea or syphilis in a communicable stage shall be imprisoned for not more than two years or fined not more than \$500. H 167 proposes to authorize the board of health to detain and examine persons suspected of being infected with a venereal disease likely to infect or to be the source of infection or another person.

Bills Passed—S 16 passed the senate, February 26. It proposes to authorize the institutionalization and treatment of persons who violate the criminal laws or who are guilty of gross immoral conduct because of mental deficiency, insanity or psychopathic personality. The latter term is defined as the existence in any person of such conditions of emotional instability or impulsiveness of behavior, lack of customary standards of good judgment or failure to appreciate the consequences of his acts as render him irresponsible for his conduct with respect to sexual or other criminal behavior and thereby dangerous to other persons. S 34 passed the senate March 9. It proposes that any person who maintains or operates a maternity hospital shall first obtain a license so to do from the department of public health. The term maternity hospital is defined as any hospital institution or place in which pregnant or parturient women and the newborn infants receive care or treatment. H 131 passed the senate March 9. To amend the osteopathic act, it proposes to authorize a recognized school of osteopathy to give a course of thirty six months rather than a four year course or at least five months in each year. H 151 passed the house March 4. To amend the premarital examination law, it proposes to authorize the execution of the required certificate by an osteopath and by a member of the medical corps of the army, navy or public health service.

Washington

Bills Introduced—H 179 proposes to prohibit any person from establishing or maintaining, outside the corporate limits of any town or city, a nursing home, rest home, home for aged or infirm persons or other similar institution without the permission of the county commissioners and authorizes the county commissioners to make rules and regulations relating to the establishment, maintenance and licensing of such institutions. H 380 proposes to prohibit the maintenance of any rest and nursing home and institution without a license from the county or city commissioners wherein the institution is located. The term rest and nursing home and institution when used in the proposal are defined as meaning any home or private institutions except hospitals approved by the American College of Surgeons or the American College of Physicians for the care and housing of aged infirm ill persons or children. H 408 proposes the creation of a sanopractic physicians examining board and defines sanopractic as the science and art of applied prophylactic and therapeutic sanitation which enables the physician to direct, advise, prescribe or apply food, water, roots, herbs, light, heat, exercises, active and passive manipulation, adjusting tissue, vital organs or anatomic structure by manual, mechanical or electrical instruments or appliances, or other natural agency, to assist nature to restore a psychologic and physiologic interfunction for the purpose of maintaining a normal state of health in mind and body. This proposal has been reported as being dead for the remainder of the current session.

Bills Passed—S J R 9 passed the house, March 2. It proposes a resolution to Congress to pass legislation establishing a pharmacy corps in the army. S 218 passed the house, March 3. It proposes to authorize the director of licenses, during the present emergency, to grant temporary certificates to practice medicine and surgery to physicians duly licensed and qualified to practice under the laws of some other state and proposes that such temporary license shall be valid from the date of issuance until the next regular examination given by the board of examiners. S 301 passed the senate, March 6. To amend the law relating to dentistry, it proposes that x-ray diagnosis and examination of the normal and abnormal structures, parts or functions of the human teeth, the alveolar process, maxilla, mandible or soft tissue adjacent thereto be declared to be the practice of dentistry.

West Virginia

Bills Introduced—S 238 proposes that no druggist shall fill any prescription containing strychnine or strychnine drug, arsenic, or arsenious oxide or "arsenic" compounds or where arsenic is "pentavalent" or neurotic or any poisonous drugs so defined by the Pharmacopeia or by the United States American or National Standard Dispensatory unless the person requesting the prescription shall first fingerprint it. Com-

mittee substitute for H 120 proposes to permit the organization of nonprofit, nonstock hospital service corporations and to authorize such corporations to furnish medical service and hospital service to subscribers. The medical service shall consist of medical and surgical care as specified in the subscriber contract issued by the corporation and shall be provided by duly licensed doctors of medicine.

Bills Passed—H 120 passed the senate, March 9. Prior to passage the proposal was amended to provide that hospital service corporations shall be declared to be scientific nonprofit institutions and exempt from taxation. H 230 passed the house on March 3 and the senate on March 10. It proposes among other things to require every physician who examines or treats a person having syphilis, gonorrhea or chancroid to instruct such person in measures for preventing the spread of the disease and to inform such person of the necessity of taking treatment until cured. If the person fails to report for treatment the physician must make a report of such fact to the local health officer.

Wisconsin

Bills Introduced—S 208 proposes to authorize a court to admit in evidence in prosecutions for operating a motor vehicle while under the influence of intoxicating liquor, testimony concerning the amount of alcohol in the accused's blood as shown by a chemical analysis of his breath, urine, or other bodily substance. S 196 proposes to authorize the state department of public welfare to establish clinics for the diagnosis of mental illness and to authorize such clinics to accept patients for hospitalization thereon on written application by such person or a relative, judge, sheriff or health officer accompanied by a medical certificate, signed by two physicians licensed to practice medicine and surgery, to the effect that the person mentioned in the application shows symptoms of mental illness other than alcoholism, inebriety, or drug addiction and appears to be in need of hospitalization. The proposal would further exempt any physician signing such a certificate from civil liability for so signing. A 33, to amend the law relating to the formation of cooperative associations, proposes that nothing therein shall interfere with the organization of voluntary associations or with contracts for medical or hospital service or both on the basis of a stipulated sum to be paid periodically. A 60 to amend the income tax law proposes to authorize the deduction to the extent not compensated by insurance or otherwise of amounts paid for professional services rendered by a doctor of medicine, dentist, osteopath or chiropractor for medicine and therapeutic treatment and amounts paid for hospitalization and care by a registered nurse other than in a hospital. A 73 to amend the income tax law proposes to authorize the deduction of payment for expenses for hospital, nursing, medical, surgical, dental and other healing services and for drugs and medical supplies incurred by the taxpayer on account of sickness or of personal injury to himself or his dependents. A 263 to amend the workmen's compensation act proposes to require that an employee who submits to an examination at the request of his employer shall be furnished with a detailed report in writing of the examining physician's findings and conclusions. A 297 proposes that every person in the practice of medicine, surgery, osteopathy or dentistry should make and maintain a written record of professional services rendered to any person who has served in the United States army, navy or marine corps or any branch thereof and shall keep such records for not less than six years after the service is rendered. A 305 proposes to require the annual registration of every person licensed to practice medicine and surgery, osteopathy or osteopathy and surgery. A 312 proposes to make counties having more than a certain population liable for medical care rendered by a physician and surgeon to certain persons entitled to such care at public expense. A 324, to amend the law relating to chiropractors, proposes that one duly licensed to practice chiropractic shall be known and designated as 'Doctor of Chiropractic' written after his name or as Doctor (his name) chiropractor or the abbreviations of either of such titles. A 327 proposes a law relating to the establishment and administration of a system of health insurance. Under the proposal the term physician would mean any person licensed to practice medicine or surgery in the state.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SPENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH.)

CALIFORNIA

Personal—Dr George D Lyman, San Francisco, was recently elected president of the California Historical Society and Dr Morton R Gibbons, San Francisco, was elected a member of the board of directors—Dr Junius B Harris, Sacramento, was recently chosen president of the California Academy of Medicine.

Popular Medical Lectures—Stanford University School of Medicine, San Francisco, announces its sixty-first course of popular medical lectures to be given at Lane Hall. The schedule will be: Drs Jacob C Geiger on "Food Rationing and Civilian Health," April 2, Alfred C Reed "Tropical Diseases Menace United States at War," April 16, Loren R Chandler, "Health Service to the Public During the Emergency," April 30, and John K Lewis, "Protection of Health and Fitness in Flying Personnel," May 14. All are of San Francisco.

New Mental Clinic—A mental clinic known as the Los Angeles Psychiatric Service has been set up in the Cedars of Lebanon Hospital, Los Angeles, through a special grant of Community Chest funds authorized by the Community Welfare Federation. Established on a one year demonstration basis, the unit is said to be the community's first psychiatric clinic for adults. It will be operated by a volunteer board of directors composed of business, professional and civic leaders interested in social welfare, of which Dr Glenn E Myers, Los Angeles, is chairman.

CONNECTICUT

Dr Thorn Gives Alpha Omega Alpha Lecture—Dr George W Thorn, Hersey professor of the theory and practice of physic, Harvard Medical School, Boston, gave the annual Alpha Omega Alpha Lecture in Brady Memorial Laboratory, Yale University School of Medicine, New Haven, February 11. His subject was "Clinical Aspects of Disturbances in Sodium Chloride Metabolism."

ILLINOIS

Society News—Dr Harry L Huber, Chicago, discussed problems in allergy before the Will-Grundy County Medical Society at Joliet March 19—The Kankakee County Medical Society was addressed, March 9, by Dr Albert Vander Kloot, Chicago, on "The Anemias."

Chicago

The Lewis Linn McArthur Lecture—Dr Chester M Jones, Boston, will deliver the nineteenth Lewis Linn McArthur Lecture of the Frank Billings Foundation on April 23 at the Palmer House. His subject will be "The Relationship Between the Nervous System and Pain Perception with Particular Reference to the Gastrointestinal Tract."

Dr William Petersen Resigns at Illinois—Dr William F Petersen recently resigned as professor of pathology at the University of Illinois College of Medicine. It is reported that Dr Petersen will devote his time to private research on the weather and its effect on human beings, a field in which he has already carried on considerable work. He was a member of the staff at Vanderbilt University School of Medicine, Nashville, Tenn., from 1914 to 1917, when he joined the medical corps of the U S Army. He joined the Illinois faculty in 1919 and in 1924 was named to a full professorship.

INDIANA

Hospital News—A three story hospital, including seven wards with a normal capacity of 180 beds, has been opened at the Indiana State Prison; the arrangement has been planned to meet the special requirements and problems confronting the medical services of a correctional institution.

Changes in Health Personnel—Dr James Carl Freed Attica, has been named health officer for Attica—Dr Earle C McBride, Terre Haute, was elected president of the city board of health—Dr James E McMeel, South Bend was elected president of the South Bend Board of Health recently, succeeding Dr George F Green, who has gone into military

service—Dr Hugh A Cowing was elected president of the Muncie Board of Health January 15. Dr Herbert D Fair was elected vice president and Dr John H Bowles was elected secretary. Dr Ferrell W Dunn and Mrs Alfred N Davis are members of the board.

LOUISIANA

University News—Franklin Bliss Snyder, LL D, Evanston, Ill., president of Northwestern University, gave the commencement address at the Louisiana State University School of Medicine, New Orleans, March 10, on "An Incident in the History of Fort Ticonderoga."

Physician Donates Rare Collection to Library—Dr Henry W E Walther, New Orleans, recently presented to the Howard-Tilton Memorial Library at Tulane University of Louisiana, New Orleans, a 700 volume collection of rare first editions, including the works of prominent English and American authors. Dr Walther graduated at Tulane's school of medicine and later served there as professor of urology.

Kenny Treatment Center—The division of crippled children of the Louisiana State Board of Health and the Charity Hospital of New Orleans are now operating a joint project in the hospital for treating acute paralytic poliomyelitis. The new service will be known as the Kenny Method Treatment Center. It will be considered a special orthopedic pediatric service treating cases of acute paralytic poliomyelitis under isolated conditions as employed in infectious diseases according to the *Bulletin* of the New Orleans Parish Medical Society. The management of patients will be carried out by members of the faculties of the Louisiana State University School of Medicine and the Tulane University of Louisiana School of Medicine, New Orleans, and the hospital staff.

MASSACHUSETTS

Physician Chosen President of Winthrop Subsidiary—Dr Bruno Thurber Guild, Boston, has been chosen president of Fairchild Brothers and Foster, a subsidiary of Winthrop Chemical Company, it was announced on February 10. Fairchild Brothers and Foster manufacture enzymes and other pharmaceutical products. Dr Guild is a past president of the Dorchester Medical Society, consultant of the Council on Pharmacy and Chemistry of the American Medical Association and councilor of the Massachusetts Medical Society.

MICHIGAN

Epidemic Keratoconjunctivitis Now Reportable—The state council of health at a meeting January 7 added epidemic keratoconjunctivitis to its list of reportable diseases. All cases or suspected cases shall now be reported to the local health officer within twenty-four hours after diagnosis.

Changes in Health Officers—Dr Frederick A Musacchio, Crowley, La., has been named director of the St Joseph County Health Department—Dr Albert C Edwards, White Cloud, director of the Fifth District health department has resigned to become head of the St Clair County Health Department—Dr Fred T Andrews has resigned as director of the health department of Bay County to become associated with the Fisher Body Division of the General Motors Corporation in Lansing—Dr George C Stucky, Charlotte, health officer of Eaton County, was recently placed in charge of the Barry County Unit. The two units were combined for the duration.

Tri-State Medical Association Meeting—The Northern Tri-State Medical Association comprising the states of Indiana, Ohio and Michigan, will hold its annual meeting at the Rackham Building, University of Michigan, Ann Arbor, April 13 under the presidency of Dr Howard H Cummings, Ann Arbor. The program includes the following speakers from the medical school at Ann Arbor:

- Dr Cyrus C Sturgis The Clinical Significance of Leukopenia
- Dr Frank N Wilson The Diagnosis and Treatment of Coronary Artery Disease
- Dr Herman H Riecker Differential Diagnosis and Management of Hypertension
- Dr Richard H Lyons The Management of the Edematous Patient
- Dr Russell N De Jong Headaches: Diagnosis and Treatment
- Dr Carl D Camp Emotional Influences on the Gastrointestinal Tract
- Dr Arthur C Curtis The Treatment of Tinea Infections
- Dr Frederick A Collier Fundamental and Clinical Consideration of Traumatic Shock
- Dr Jack Matthews Farris The Use of Reduced Temperatures in the Management of Peripheral Vascular Disease
- Dr Reed M Nesbit Present Status of Hormone Therapy for Cancer of the Prostate
- Dr F Bruce Fraclik Discussion and Questions Commonly Asked About the Eyes by Patients
- Dr Albert C Furstenberg Complications of Acute Upper Respiratory Infections
- Dr Norman F Miller Caudal Anesthesia in Obstetrics

NEBRASKA

State Meeting Canceled—The Nebraska State Medical Association will not hold an annual session in 1943. A meeting of the house of delegates will be held in Lincoln May 4. Members wishing to attend this session will be welcome.

NEW YORK

Changes in Hospital Management—Newspapers recently reported that St. Mary's Infant Asylum and Maternity Hospital, Buffalo, will be converted into a hospital for infants and children only and that the Central Park Hospital, Buffalo, was to be taken over, February 1, by the Sisters of St. Francis. It was also reported that the Providence Retreat, Buffalo, for the treatment of mental and nervous disorders will be used exclusively for maternity cases in the future. Both the Retreat and St. Mary's hospitals are owned and operated by the Sisters of Charity; the report stated. The name of the Providence Retreat will be changed. The shifting of these facilities was carried out because of the need for an additional maternity hospital in the area.

New York City

Meeting of Hispanic-American Medical Society—The annual meeting of the Hispanic American Medical Society of New York will be held at the New York Academy of Medicine on March 23. A symposium on hypertension will make up the program with Dr. Irvine H. Page, Indianapolis, presenting a paper entitled "Is Essential Hypertension of Renal Origin?" Dr. George J. Heuer, "Value of Surgery in the Treatment of Hypertension" and Domingo M. Gomez, formerly of Paris University, Paris, France, "Hemodynamics and Mean Pressure."

New Committee on Psychosomatic Medicine—The Kings County Medical Society and the Academy of Medicine of Brooklyn have announced the organization of a committee on psychosomatic medicine to arrange a teaching program in psychosomatic medicine for practicing physicians and to establish in local hospitals personnel trained in psychosomatic medicine who will be available for therapy and research. The committee consists of a chairman who is an internist with a psychoanalytic orientation, two psychiatrists, a cardiologist, a urologist, a gastroenterologist and a gynecologist. Others will be added as the need arises. Members include Drs. A. Nathaniel Rosen, Brooklyn, chairman; Irving J. Sands, Brooklyn, and Howard W. Potter, psychiatry; Alfred C. Beck, Brooklyn, obstetrics and gynecology; Leo S. Drexler, Brooklyn, urology; Henry F. Kramer, Brooklyn, gastroenterology; and Louis H. Sigler, Brooklyn, cardiology.

Goldwater Fund for Fellowship in Hospital Administration—Under the will of the late Dr. Sigismund S. Goldwater, a sum of money was left to Mount Sinai Hospital, which, together with gifts from Mrs. Goldwater and friends of Dr. Goldwater, will provide an income of \$1,000 annually to establish a fellowship in hospital administration and will be known as the Dr. S. S. Goldwater Memorial Fund. Recipients will receive the stipend of \$1,000 during the year of appointment and be provided with residence in the hospital if an unmarried person. It will be made available to serious students and workers in hospital administration and should prove of most benefit to some one already in the field in a junior and even senior position. Previous hospital background and experience would provide an important foundation for the fellowship which should prove especially useful to junior hospital administrators with a present hospital connection, who can secure a year's leave of absence if selected and who can return to their positions. The fellows' daily activities will be fitted to his own needs for hospital training and to his own capacities. Applications are now being accepted, since funds for the stipend are now available; the selection to be made by the board of trustees of the hospital. The benefits of the fellowship will not be limited to Mount Sinai Hospital.

OHIO

Dr. Mann Gives Alpha Omega Alpha Lecture—Dr. Frank C. Mann, professor of pathology and experimental physiology, and surgery, University of Minnesota Graduate School, Rochester, Minn., delivered the Alpha Omega Alpha Lecture in the Institute of Pathology, Cleveland, March 12 on "The Value of Research in Medical Education."

Annual Meeting of State Society—"Medicine on the Home Front" will be the theme of the ninety-seventh annual meeting of the Ohio State Medical Association at the Neil House, Columbus, March 30-31. Dr. Edward J. McCormick, Toledo, president of the association, will speak on "Adjustment of the Physician to Civilian Needs in Wartime." One

session on "Medicine and the War" will be addressed by Drs. Robert Conard, Wilmington, Elmer L. Henderson, Louisville, Walter F. Donaldson, Pittsburgh, and Harold S. Diehl, Minneapolis. There will be general sessions on "Keeping them Working," featuring a symposium of subjects pertaining to industrial health with the following speakers:

Ralph Christopher Jeggio, Columbus, surgeon, U. S. Public Health Service Reserve, director, industrial hygiene service, state department of health, Present Day Influences in Industrial Health.

Dr. Carl M. Peterson, Chicago, Secretary, Council on Industrial Health, American Medical Association, Essentials and Organization of Industrial Health Services.

Dr. Henry Close Hesselstine, Chicago, Women in Industry—Present and Future Problems.

A general session devoted to "Keeping them Healthy" will be addressed by Drs. Tom D. Spies, Cincinnati and Birmingham, Ala., on "Importance of Optimum Nutrition for the Civilian Population in Wartime" and John A. Toomey, Cleveland, "Importance of Immunization of the Civilian Population in Wartime." All sessions of the Women's Auxiliary to the state medical association will be held at the Deshler-Wallick Hotel on March 30.

VIRGINIA

Institutes on Industrial Medicine—The department of clinical and medical education and the committee on industrial health of the Medical Society of Virginia are cooperating in a series of five one-day institutes on industrial medicine in the Tidewater area. Meetings are being arranged at Newport News, March 22; Norfolk, March 23; Portsmouth, March 24; Suffolk, March 25; and Petersburg, March 26, under the sponsorship of the Peninsula Academy of Medicine, Elizabeth City; City Medical Society, Norfolk; County Medical Society, Portsmouth; Medical Association, Nanamond County; Medical Society and the Fourth District and Southside Virginia medical societies. The program will include the following speakers:

Dr. Orlen J. Johnson, Chicago, Industrial Medicine Today.

Dr. Hark L. Stephenson, Richmond, Compensation.

Drs. Everett L. Evans and Milton J. Hoover, Jr., both of Richmond, Trauma Shock and Burns.

Dr. William I. Weaver, Richmond, Industrial Medicine.

John E. Dunn, Jr., passed assistant surgeon, U. S. Public Health Service, Bethesda, Md., Dermatitis.

WASHINGTON

Changes in Health Officers—Dr. Arthur L. Ringle, Portland, Ore., has been appointed district health officer with headquarters at Walla Walla to succeed Dr. John A. Kahl. Dr. Willis E. Smick, Seattle, has been named health officer of Cle Elum.

Society News—The Walla Walla Valley Medical Society recently was guest of the Veterans Administration Facility at Old Fort Walla Walla. Dr. Oliver M. Warner, Walla Walla, discussed "Diphtheritic Hemina" and Lieut. Karl W. Pleissner, M. C. U. S. Army, "Protection in Gas Warfare and Treatment of Casualties." Dr. Robert D. Forbes, Seattle, discussed "Progress in Abdominal Surgery" before the King County Medical Society, March 1. The society will be addressed, April 5, by Drs. Julius A. Weber on "Atelectasis of the Lungs Postoperative and in the Newborn," and Thomas W. Blake, "Some Nontuberculous Pulmonary Conditions," both are of Seattle.

WISCONSIN

Appointments to State Board of Health—New members of the Wisconsin State Board of Health are Drs. Albert E. Rector, Appleton, to succeed Dr. Joseph Dean, Madison; Dr. Ira F. Thompson, Racine, to succeed Annala C. Burd, R.N., Eau Claire; Dr. Gunnar Gundersen, La Crosse, to succeed Dr. Cornelius A. Harper, Madison, who resigned as state health officer and as member of the board; and Dr. William T. Clark, Janesville, to succeed Dr. Robert L. McCormack, Whitehall. Dr. Carl N. Neupert, Madison, is the new state health officer (THE JOURNAL, January 30, p. 364).

Mickle Fellowship Awarded to Dr. Tatum—The Charles Mickle Fellowship for 1942 at the University of Toronto, Canada, has been awarded to Dr. Arthur L. Tatum, since 1928 professor of pharmacology, University of Wisconsin, Madison. The award went to Dr. Tatum as the member of the medical profession who has done most during the preceding ten years to advance sound knowledge of a practical kind in medical art or science. Dr. Tatum received his degree at Rush Medical College, Chicago, in 1914, having earned his Ph.D. at the University of Chicago in 1913. He has served as professor of pharmacology at the University of South Dakota and as assistant professor of pharmacology at the University of Chicago. In 1937 he was chosen president of the American Society of Pharmacology and Experimental Therapeutics.

GENERAL

Association of Anatomists—The 1943 meeting of the American Association of Anatomists scheduled to be held at McGill University Faculty of Medicine, Montreal, has been canceled. As first vice president of the association Dr J Parsons Schaeffer, Philadelphia, assumes the responsibilities of president of the association to succeed the late Edgar Allen PhD New Haven, Conn., and Dr Elton R Clark, Philadelphia has been named secretary-treasurer to succeed the late Francis H Swett PhD, Durham, N C. Sectional meetings of the association will be held in Philadelphia and Chicago in April.

Dr Bing Joins Institute of Baking—Irwin C Bing, PhD, Secretary of the Council on Foods and Nutrition of the American Medical Association, Chicago, has been appointed director of the American Institute of Baking, Chicago effective March 15. Dr Bing was born in Montgomery County near Philadelphia Dec 29 1902. He received his doctor of philosophy degree at Yale University New Haven Conn in 1930. Prior to joining the American Medical Association in February 1936 Dr Bing had been a member of the staff of the department of biochemistry at Western Reserve University, Cleveland. He is assistant professor of physiology at Northwestern University Medical School and a member of the Food and Nutrition Board of the National Research Council Washington, D C.

Conference of State and Provincial Health Authorities—The forty-eighth annual Conference of State and Provincial Health Authorities of North America will be held at the District Medical Society Building Washington D C March 23, under the presidency of Dr Carl V Reynolds Raleigh N C. Among the speakers will be

Drs Stanley H Osborn Hartford Conn John T Phair Toronto Ontario and James G Townsend Bethesda Md Industrial Health
Dr Frederick W Jackson Winnipeg Manitoba Wilton L Baker San Sacramento Calif George Bach Washington and Albert S McCown Washington National Defense and Disaster Relief
Dr George W Cox Austin Texas and Malcolm R Bow Edmonton Alberta John K Hoskins Cincinnati Environmental Sanitation
Drs John F Kendrick Raleigh Gregoire F Amyot Victoria B C and William H Schrell Jr Bethesda Nutrition
Dr Elmer Dr Roland R Cross Springfield Ill A W Fuchs C F Washington and Ollie E Reed MS Washington Milk
Dr Henry Hanson Jacksonville Fla Antonio Fernos-Iscorn San Juan P R and Kolff F Dyer Bethesda Tropical and Subtropical Diseases

A feature of the meeting will be the presentation of honorary life membership to Dr Cornelius A Harpur Madison, recently retired as health officer of Wisconsin. Meetings for which a program is not available will be those called by Dr Thomas Parran, surgeon general of the U S Public Health Service, Washington, on March 24, and by Katharine F Lenroot LL D, chief of the Children's Bureau Washington, March 25.

Board of Orthopedic Surgery Revises By-Laws—The American Board of Orthopaedic Surgery announces that under a revision of its by-laws now under way the examination will be divided into parts I and II. Applicants who have completed a rotating internship and one or two years of resident training in orthopedics or their equivalent in military service will be eligible for part I of the examination. This part will cover the basic sciences, fundamentals of surgery and elementary principles of orthopedic and fracture treatment with oral interviews and written examination. Tentative plans provide that part I may be given during the fall months in four different centers, probably in New York, Chicago, New Orleans and San Francisco. Part II of the examinations will probably be given as heretofore only once a year in connection with the meeting of the American Academy of Orthopaedic Surgeons. Applicants for part II must have completed their full requirements for eligibility, including their practice periods. The written examination and oral interviews will include advanced operative technique, standard orthopedic procedures, reviews of the literature and case records. Certification by the board will follow successful completion of part II of the examination. In order that the committee on eligibility may have adequate data for evaluation of the training of applicants who have served with the armed forces a plan will be set up whereby all who are assigned to orthopedic services will be provided with an orthopedic service record. This record must indicate the character and amount of orthopedic work performed at each post to which prospective applicants are assigned. The fee schedule is also being revised. The board announces the revised rulings will be published and distributed by July 1943 so that prospective candidates may be governed accordingly. The dates of future examinations will be published at the same time. Dr Guy A Caldwell, 3503 Pryor Street New Orleans, is secretary of the board.

Report of American Red Cross—The expanded services of the American Red Cross to meet the needs occasioned by the United States' participation in World War II are outlined in the organization's annual report for the year ended June 30, 1942. Since the organization of the first camp and hospital service council at Fort Dix in July 1941 the program has been extended during the year to seventy-three councils representing 817 chapters and approval was given to about thirty-five additional councils. Full time representation was made available at eighteen regional offices out of fifty-three served and additional services will be developed as the need increases. On July 1, 1941 the personnel of services to the armed forces totaled 641 while on June 30 1942 the total was 3088 an increase of 381 per cent. On June 30 1942 the hospitals in continental United States were staffed with 527 workers as follows: 178 medical social psychiatric social and other social workers 166 recreation workers and 183 clerical personnel. The bureau of army affairs handled 18780 cases as compared with 4289 for the previous year the increase caused mainly by inquiries from families of service men concerning their welfare after Pearl Harbor. Information was requested from the War Department on 6758 service men as compared with 737 similar requests during the previous year. Tremendous increases were also noted in similar services by the bureau of naval affairs.

From July 1, 1941 to June 30 1942 the Red Cross extended relief in 172 disasters in forty-two states. In all 72 434 persons were aided at a total expenditure of \$1 233 292 37. Disasters in continental United States for the year number fifteen more than the peak year of 1938-1939, when the total reached 157. Though most of the disasters were minor in point of numbers of families affected the large number of operations necessitated an expenditure for disaster relief of \$286 668 81 in excess of the \$946 626 56 spent during the previous year. The largest single operation was necessitated by a series of destructive tornadoes which struck during the week of March 15 1942 in fifty-two counties of Mississippi, Tennessee, Alabama Kentucky, Indiana and Illinois. The Red Cross provided rehabilitation assistance for 1077 families out of a total of 2249 affected. Ninety per cent of the assistance was given to farm families. One hundred and fifty-one persons were killed 600 were seriously injured and 500 received minor injuries. Of the 442 hospitalized only seventeen remained in hospitals June 1 1942. Thirty-eight disasters were caused by tornadoes and floods in Arkansas Colorado, Illinois Indiana Kansas Missouri Minnesota Nebraska North Dakota South Dakota Oklahoma, Texas Wisconsin Iowa and Michigan the largest number of disasters for a like number of days in the history of the Red Cross. The greatest disaster of the year in a single community occurred in Pryor Okla. April 27 when a tornado killed 44 persons and injured 277. Hospitalization was necessary for 225 of the injured. From April 20 to 22 thirteen counties in the central part of east Texas were affected by the heavy rise in waters of the Trinity River and its tributaries. The Red Cross assisted 2034 with emergency and rehabilitation relief of the 3430 families affected.

During the year 778 Red Cross public health nurses, paid in full or in part from chapter funds have cared for 242 052 patients, requiring a total of 897 260 visits to homes to physicians and to agencies in behalf of patients and to individuals receiving health supervision. 306 chapters sponsored 441 nursing services. More than 348 nurses gave a total of 3 093½ days of service in thirty-one disaster relief operations.

In its participation in the development of blood donor service, the Red Cross has centers in New York, Philadelphia, Baltimore Buffalo Rochester, N Y Indianapolis, Detroit, Pittsburgh, St Louis Cincinnati, Brooklyn and Washington, D C.

During the year 1731 chapters with a staff of 16 093 nutritionists and instructors offered the standard nutrition and canteen courses. The organization has cooperated with state nutrition committees in providing refresher courses, the activities of the Red Cross in this field being primarily educational. A total of \$25 309 738 17 was expended by the American Red Cross in carrying out its various programs of aid and maintenance of organization.

CORRECTION

School of Tropical Medicine of the University of Puerto Rico—In the item concerning the Ashford General Hospital in the Medicine and the War section of THE JOURNAL February 20 page 599, the year in which the School of Tropical Medicine of the University of Puerto Rico was established was erroneously given as 1936. This school was opened in September 1926 (THE JOURNAL, July 31, 1926, p 332).

Cancer Research

Like most of our ordinary activities, cancer research goes on notwithstanding the war. At the nineteenth annual meeting of the British Empire Cancer Campaign reports from twenty-four research departments or branches in this country and from eleven overseas were announced. The finding by Bittner in the milk of female mice of high cancer strain a factor concerned in the development of spontaneous breast cancer gave rise in the department of experimental pathology and cancer research of the University of Leeds to a study of the effects of estrogenic stimulation on male mice. The newborn of high breast cancer were at once transferred to mothers of low breast cancer strain, and vice versa. After weaning injections of triphenylmethylene were made and continued until death. The results showed an almost complete reversal of the expected incidence of cancer. Of the mice which died only 1 mouse suckled by a low breast cancer foster mother developed breast cancer whereas all but 3 of the low breast cancer mice suckled by a high breast cancer foster mother died of breast cancer. In another laboratory, at Newcastle on Tyne the incidence of breast cancer in mice of low cancer strain was raised from 5 to 60 per cent by fostering them on females of high cancer strain.

The clinical research committee of the campaign has analyzed 473 cases of cancer of the esophagus registered in London hospitals during 1938 and 1939. In 67 per cent the first symptom was dysphagia; in the remainder misleading symptoms led to mistaken diagnosis. Radical surgery was possible in only 5 cases. Exploratory operations had a high mortality. Radium treatment was disappointing. Of the 473 cases 399 were fatal in the first year, 19 in the second and 5 in the third. Sixty-five cases of postcricoid carcinoma were also analyzed; there were 56 deaths in the first year from the beginning of treatment, 3 in the second year and 1 in the third. Two of the remaining patients are known to be still alive and 3 are untraced. A curious sex difference was found between the two groups. Of the patients with postcricoid cancer 54 (83 per cent) were female, whereas of the 473 with esophageal cancer only 76 (16 per cent) were female. The mean age of the postcricoid patients was 65 years for males and 55 for females; of the esophageal patients 64 for males and 61 for females.

The Royal College of Physicians and Housing Schemes

Before the war the health authorities were engaged in a housing effort which was producing over three hundred thousand houses annually. This had to be suspended because of the war, after which there will be an accumulated deficiency. Steps are already being taken to start again on the cessation of hostilities. The Ministry of Health has appointed a central advisory committee which is drawing up a program. At its request the Royal College of Physicians has given advice on features which have a bearing on health. A committee of the college states that in planning the importance of sunshine, warmth, light and air must be considered. In cottage estates the rooms most commonly used, at least one of which should be a bedroom, should face south to southeast. In block dwellings the major axis should run from north to south so that the majority of flats face east and west. 'Wells' which overshadow one block by another should be avoided.

The main health feature of structure is complete protection from dampness. Care should be taken to prevent noise and the siting of windows should be governed more by the calls of

health than by external symmetry. The college does not regard as adequate the present standards of floor space and area of rooms. It recommends that in a house of three bedrooms no room used for sleeping should be smaller than 100 square feet and that the second bedrooms, presumably to be used for children, should be as large as the first. A local authority should reject plans of a new house or extension of a house unless baths with a piped supply of hot and cold water and a sink with hot and cold water are provided. A living room in which neither cooking nor washing is carried out is essential, and three bedrooms should be the minimum for all families of two or more persons, except aged couples. In the reconstruction of cities there are great opportunities for providing open spaces.

The college, being concerned for the protection of children from traffic dangers, the promotion of community health centers and community feeding, and services for social health, recommends that housing estates should be grouped on a community basis. In populous areas at any rate provisions should be made for cheap, wholesome meals. All the services for preventive medicine including infant welfare, school health services and supervision of adolescents and industrial workers, should be brought together as a health center under one roof.

The Wartime Increase of Tuberculosis

A recent report of the Medical Research Council shows an increase of deaths from tuberculosis since the beginning of the war in all age groups. The report states that under war conditions primary infection among those who have reached adult life uninfected has probably increased. It therefore urges that physicians should pay special attention to all cases of pleurisy, erythema nodosum and phlyctenular conjunctivitis. Such cases, as well as those of hemoptysis without apparent cause, should be referred to the tuberculosis officer for full investigation, follow-up examinations and search for source of infection within their families. The importance of this is shown by a survey of 2,000 patients with tubercle bacilli in their sputum. Of these, 27 per cent had a history of untreated pleurisy or hemoptysis three or four years before a diagnosis of pulmonary tuberculosis was made. Physicians are also asked to refer cases of suspected glandular, abdominal and other nonpulmonary tuberculosis to the tuberculosis officer for radiography of the chest, so that search for contacts may be made.

The Functions of the Pyloric Canal

At a meeting of the Section of Anatomy and Physiology of the Royal Academy of Medicine in Ireland, Dr. J. W. Millen drew attention to the importance of the pyloric canal as a distinct region of the stomach which differed in anatomy, mobility and function from the other parts. In the normal stomach three parts could be recognized: (1) a region for reception and storage, which was present in all but the lowest invertebrates, (2) a terminal closing mechanism—the pyloric sphincter—which assisted in the maintenance of storage, and (3) an active milling region—the pyloric canal—for the trituration and fine subdivision of food. The storage region comprised the body and fundus and the more or less well defined pyloric antrum for the active filling of the pyloric canal.

Roentgenograms of the stomach of a young adult showed that in the early stages of canalization by an opaque meal the food did not at once enter the pyloric canal. When a small amount of the meal was manually pressed into the pyloric canal, the longitudinal folds of the mucous membrane could be seen in the canal and the pyloric sphincter was well defined. After about half a pint of the meal had been given, further roentgenograms showed that the pyloric canal had become rounded and globular but was still a separate region filled from the pyloric antrum by deep peristaltic waves which traversed it. But in about a third of dissecting room subjects examined no pyloric canal could be defined, the whole stomach being a single cavity.

In the remaining two thirds the normal subdivisions as described were found. The absence of a pyloric canal in the former group might be due to its incorporation in the proximal part of the stomach and represent a shift toward the single chamber of adult carnivores.

The pyloric canal therefore had two functions—as an active milking region and in the emptying of the stomach, either as an active or as a passive region coordinated with the body of the stomach. Congenital hypertrophic stenosis of the pylorus was a hypertrophy of the pyloric canal not of the pyloric sphincter. It might therefore be due to the pyloric canal functioning as a mill but failing to act in harmony with the proximal part of the stomach in its function as part of the emptying mechanism.

Cooperation of Rheumatism Specialists and Orthopedic Surgeons

Rheumatism in its various forms is so prevalent as to be a national problem. The Empire Rheumatism Council and the British Orthopedic Association have agreed that their mutual cooperation in the diagnosis, prevention and treatment of crippling conditions would be of great service to the community. They run at a close liaison between the physician specializing in rheumatism and the orthopedic surgeon seeking to enlist the cooperation of the general practitioner, the public health services and social workers generally. They hold that orthopedic hospitals and orthopedic departments of general hospitals should have on their staffs a physician with special knowledge of rheumatic diseases and that rheumatism centers should have on their medical staffs an orthopedic surgeon. Since the application of methods of physical and occupational therapy for orthopedic and rheumatic patients is largely identical a joint outpatient clinic should, wherever practicable, serve for both classes of patients.

In view of the growing appreciation of the regionalization of medical services, the scheme for the rheumatism treatment centers should be planned to fit into such schemes as may be arranged for the future. This has already been done in orthopedic schemes, in which the development of the centers is based on the legal requirements of the notification of certain crippling diseases and on the public responsibility for the provision and payment for their treatment. So in rheumatic diseases a similar responsibility should be assumed by the state and the local authority. Provision for the training of young physicians and surgeons in research, diagnosis and treatment should be associated with suitable encouragement to make the study of rheumatic disease a life work. To put into effect the agreed plan of cooperation a joint standing committee of eminent rheumatism specialists and orthopedic surgeons, under the chairmanship of Lord Horder, has been appointed.

Road Accidents in 1942

The road accidents for December were the highest of any month of 1942: 780 killed and 12,842 injured compared with 1024 killed and 18,300 injured in December 1941. Since the war the December accident peak has been more pronounced because of the blackout accidents. Last December nearly three fourths of the pedestrians killed, other than children, lost their lives during the hours of darkness. Fatalities to children, including cyclists, numbered 109, and 1,650 were injured.

The number of deaths on the roads of Great Britain in 1942 was 6,926. This is a decrease of nearly a fourth compared with 1941, but not so great as might have been expected considering the fewer vehicles on the road. Early in 1941 the danger of road accidents was increased by the heavy enemy night raids and consequent hurry to get home.

During 1942, 1,315 children were killed, against 1,462 in 1941. A possible cause of the high proportion of accidents to children is that many persons are engaged in war work and cannot exercise the supervision they would give in normal times.

BRAZIL

Feb 26, 1943

The Work Against Yellow Fever in Brazil

The 1941 annual report of the National Yellow Fever Service of Brazil contains interesting information. Up to 1930, when the Vargas regime began in Brazil, the control of yellow fever was the duty of various authorities and this continued until Dec 31, 1941, when the government obtained the cooperation of the International Health Board of the Rockefeller Foundation. The work was then reorganized and unified, with the creation of a new organization under the name of National Yellow Fever Service. This is an extensive single organization dealing with an important health problem particularly since the discovery of the widespread sylvatic form of the disease. The practical results of the new organization were such that several countries of South America followed the example of Brazil, putting all the control measures of yellow fever under the technical guidance of Dr Fred L. Soper of the Rockefeller Foundation, with Rio de Janeiro becoming the coordinating center of the whole work. In 1932 a complete code of the control measures was approved by the Brazilian federal authorities, and such a code has been lately adopted by several foreign governments, as those of Argentina, Bolivia, British Guiana, Colombia, Ecuador, Paraguay, Peru and Venezuela. The Brazilian service has functioned as a training school for medical officers and technicians from the United States as well as from Argentina, Bolivia, British Guiana, British colonies of Africa, Belgium, Colombia, Cuba, France, Germany, Peru and Venezuela. For the first time in campaigns against yellow fever, a technique of intensive specific measures has been created against *Aedes aegypti* (Stegomyia), that resulted in the eradication of this species of mosquito from extensive areas. For a few years there have been no stegomyias in six of the twenty states of Brazil and the Federal District (Rio de Janeiro city), and in the rest of the country the stegomyia index (percentage of water deposits presenting larvae and pupae) is very low. For the control of *Aedes aegypti*, more than 338 million inspections of dwellings and almost 2 billion inspections of water deposits have been done between 1932 and 1941. The service expects that Brazil with its 3,228,000 square miles and 45 million inhabitants will be free of the stegomyia mosquito within a few years. From 1941 to the present, no more cases of stegomyia transmitted yellow fever have been registered.

But the control of the stegomyia is important only in urban and suburban areas, because for a decade it has been known that many cases of illness occurring in the forested areas were true cases of the same urban yellow fever, but the infection was not transmitted by *Aedes aegypti*. Evidence has accumulated that the mosquitoes *Aedes leucocelaneus*, *Hemagogus capricornus* and *Sabethinus* are responsible for the transmission of the disease in the jungles, where any mosquito control work is impracticable. The control of the sylvatic form of the disease depends on the extensive use of viscerotomy and of vaccination (THE JOURNAL, Jan 10 1942, p 159). There are now more than 1,500 localities where the service of viscerotomy is performed as a routine measure, and more than 30,000 samples of liver have been examined by the pathologic laboratory annually since 1938. To help in the epidemiologic investigations, more than 9,000 samples of blood serum have been used annually since 1939 in the performance of the white mouse protection test. The most effective measure to protect the rural population against yellow fever is immunization. The report shows that 158,034 vaccinations were performed in 1941 thus raising to more than 2 million the total of persons vaccinated against yellow fever since 1938. The annual number of jungle cases of the disease has been 263 in 1938, 130 in 1939, 172 in 1940 and only 19 in 1941. According to the latest information just a few cases have been recognized during the year 1942.

Deaths

John Finch Barnhill, Miami Beach, Fla. Central College of Physicians and Surgeons, Indianapolis, 1888, practiced in Indianapolis since 1888 and specialized in surgery of the head and neck, since 1930 professor emeritus of surgery of the head at the Indiana University School of Medicine, where he had been professor of otology, laryngology and rhinology and later professor of surgery of the head and neck. In 1927 retired after thirty-eight years service as a teacher at the university and its predecessor, continuing in an advisory capacity. Was an honorary professor of anatomy at the University of Southern California School of Medicine, Los Angeles, specialist certified by the American Board of Otolaryngology, secretary of the Section on Laryngology and Otology, 1901-1903 and chairman in 1903-1904 of the American Medical Association and member of its House of Delegates in 1905 and in 1920 vice president of the American Ear, Throat and Nose Association in 1908, charter and honorary member of the Indianapolis Ophthalmological and Otolaryngological Society, member and in 1931 president of the American Academy of Ophthalmology and Otolaryngology, member and in 1928 president of the American Laryngological Rhinological and Otolological Society, member and in 1937-1938 president of the American Laryngological Association, member of the American Otolological Society, Inc., fellow of the American College of Surgeons, served as ear, nose and throat consultant at the City and Deaconess hospitals, Indianapolis, on the editorial board of the *Archives of Otolaryngology*, author of a textbook on Nose, Throat and Ear, co author of *Principles and Practice of Modern Otology*, 'Surgical Anatomy of the Head and Neck' and other books, received the LL.D. from his alma mater and the Indiana University in 1929, aged 78, died March 10.

William Anderson Snodgrass, Little Rock, Ark., Arkansas Industrial University Medical Department, Little Rock, 1897, emeritus professor of surgery at the University of Arkansas School of Medicine, at one time professor of principles of surgery and clinical surgery at the College of Physicians and Surgeons, Little Rock, past president and for many years a member of the State Medical Board of the Arkansas Medical Society, past president of the Pulaski County Medical Society, fellow of the American College of Surgeons, formerly secretary of the board of health of Pulaski County, at one time city physician, veteran of the Spanish American War, organized and accompanied the Red Cross Hospital Unit T to England, served as a major in the medical corps of the U. S. Army during World War I and received the Distinguished Service Medal for bravery during the battle of the Marne, formerly secretary and general medical manager of the College of Physicians and Surgeons Hospital, on the staffs of the Little Rock General Hospital, Children's Hospital and the Baptist State Hospital, where he died, January 4, of myocarditis and hypostatic pneumonia, aged 68.

James Alexander Clarke Jr., Philadelphia, Jefferson Medical College of Philadelphia, 1918, specialist certified by the American Board of Internal Medicine, associate in medicine at his alma mater, assistant in medicine at the Columbia University College of Physicians and Surgeons, New York, 1918-1919 and assistant in clinical pathology from Feb. 1, 1919 to June 30, 1919, member of the American Association for the Study of Allergy and the Philadelphia College of Physicians, past president of the Society for the Study of Asthma and Allied Conditions, chief of the allergy service at the Germantown Dispensary and Hospital, formerly on the staffs of the Vanderbilt Clinic and the Roosevelt Hospital, New York, and the Seaside Hospital of St. John's Guild, Staten Island, since Sept. 27, 1922 on the staff as consultant in allergy at the Veterans Administration Facility for many years, assistant physician on the staff of the Philadelphia General Hospital, chief clinical assistant in the department of applied immunology at the Jefferson Hospital, where he died, January 31, of carcinoma, aged 51.

Lorenzo Nelson Grosvenor, Huron, S. D., Chicago Homeopathic Medical College, 1889, Rush Medical College, Chicago, 1902, member of the House of Delegates of the American Medical Association in 1931, member and in 1930 president of the South Dakota State Medical Association, fellow of the American College of Surgeons, past president and secretary of the Huron District Medical Society, specialist certified by the American Board of Ophthalmology, at one time practiced in Chicago, where he had been instructor of ophthalmology at Rush Medical College, on the staff of the Illinois Charitable Eye and Ear Infirmary and a member of the Chicago Ophthalmological Society, superintendent of the

Beadle County Board of Health, aged 74, died recently in Rochester, Minn., of coronary occlusion and hypertrophy of the prostate.

Edward Henry Risley, Loma Linda, Calif., American Medical Missionary College, Chicago, 1904, Medical Department of the University of California, San Francisco, 1911, dean, professor of chemistry, member of the board of trustees and past president of the College of Medical Evangelists, instructor in chemistry, 1905-1906, and professor of chemistry from 1906 to 1910 at the American Medical Missionary College, Battle Creek, Mich., president of the San Bernardino County Medical Society, on the staff of the Loma Linda Sanitarium and Hospital, co author of 'The Food Question,' 'Foods Nutrition and Clinical Dietetics' and 'Home Physician and Guide to Health,' aged 61, died, February 7, of cerebral hemorrhage and arterial hypertension.

William Pitt Baker, Pine Bluff, Ark., Arkansas Industrial University Medical Department, Little Rock, 1891, graduated from the West Point Military Academy in 1887 and joined the Tenth Infantry at Fort Union, New Mexico Territory, in the same year, was active in organizing the First Infantry of the Oklahoma National Guard, served during the Spanish American War, the Boxer Rebellion in China and World War I, was chief surgeon and chief of the Information Division of the Philippine Islands Constabulary, formerly professor of medical chemistry and toxicology at his alma mater now known as the University of Arkansas School of Medicine, mayor of Rosboro for six years, aged 79, died, December 11.

Sylvester James McNamara, Brooklyn, Long Island College Hospital, Brooklyn, 1892, member of the Medical Society of the State of New York, past president of the South Brooklyn Medical Society and the Brooklyn Gynecological Society, fellow of the American College of Surgeons, consultant at the Kings Park (N. Y.) State Hospital and the Concy Island Hospital, consulting obstetrician and gynecologist at the Kings County Hospital, consulting obstetrician and gynecologist and for many years secretary of the council of the Long Island College Hospital, where he died, January 31, of coronary thrombosis, aged 73.

Margaret Schulze, San Francisco, University of California Medical School, San Francisco, 1916, specialist certified by the American Board of Obstetrics and Gynecology, Inc., member of the Pacific Coast Society of Obstetrics and Gynecology, fellow of the American College of Surgeons, assistant professor of obstetrics, gynecology and pathology at her alma mater, visiting pathologist, obstetrician and gynecologist, University of California Hospital, assistant visiting obstetrician and gynecologist, San Francisco Hospital, visiting gynecologist, Laguna Honda Home, aged 48, died, February 7, of acute hemorrhagic pneumonia.

Caswell C. Turner, Glasgow, Ky., University of Louisville Medical Department, 1910, president elect of the Kentucky State Medical Association, served as president and secretary of the Barren County Medical Society and for two terms as the councilor of the Third District, during World War I served as a captain in the medical corps of the U. S. Army, in charge of internal medicine at the Samson Community Hospital, a member of the board of the Glasgow Library Association and chairman of the Barren County Board of Health, aged 59, died suddenly, February 28, of angina pectoris.

Samuel Stanley Dorrance, Albany, N. Y., Albany Medical College, 1938, Dorrance Fellow in medical research, Johns Hopkins University, 1941-1942, served as assistant professor of physiology and pharmacology and associate in medicine, Albany Medical College, since September 1942, employed by the Transcontinental and Western Air, Inc., as a flight surgeon for a contract carrier operating under the Army Air Transport Command, aged 30, was killed in an air transport crash, January 15, in Dutch Guiana while on his way to conduct a medical survey in South America and Africa.

Willard Geist Mengel, Camden, N. J., University of Pennsylvania School of Medicine, Philadelphia, 1921, assistant professor of ophthalmology at the Medico Chirurgical College, Graduate School of Medicine, University of Pennsylvania, Philadelphia, specialist certified by the American Board of Ophthalmology, member of the American Academy of Ophthalmology and Otolaryngology, for many years on the staff of the Wills Hospital, Philadelphia, ophthalmologist on the staff of the Camden County General Hospital, Grenloch, aged 46, died, January 7, of coronary occlusion.

Francis Normer Andrews, Branchville, S. C., Medical College of the State of South Carolina, Charleston, 1925, member of the Medical Society of the State of North Carolina, served during World War I, aged 43, was killed, January 19, when his automobile overturned.

William A Applegate, Washington, D C, Harvard Medical School, Boston, 1882, in 1937 retired as chief surgeon of the Southern Railroad after holding the position for thirty-two years, aged 85, died, December 18

Eugene Hiram Ash, Canton, Mo., Fort Wayne (Ind) College of Medicine, 1901, aged 70, died, December 5, in Iowa City of hemorrhage of the stomach

Willis Alonzo Bird, Herdland Ala., Chattanooga (Tenn) Medical College, 1895, aged 76, died, January 12

Daniel Heister Bradley, Pittman, N J, Hahnemann Medical College of Philadelphia, 1872, aged 93, died, January 30, of senility

Arthur Richard Braunlich, New York, College of Physicians and Surgeons, New York, 1894, formerly associated with the department of health as a diagnostician and consulting physician at the City Hospital, for many years attending physician on the staff of the Riverside Hospital, the Willard Parker Hospital and St Francis' Hospital, where he died, January 8, aged 74

Daniel William Collins, Wilkes-Barre, Pa. College of Physicians and Surgeons, New York, 1888, aged 76 died, January 8

William Wilder Cook, Quincy, Mass Tufts College Medical School Boston 1910, practiced at Maracubo, Venezuela, and in the Panama Canal Zone for many years, aged 56, died, January 23, of coronary occlusion

William E Crutcher, Fort Myers, Fla., University of Louisville (Ky) Medical Department, 1891, aged 77, died, January 4 of heart disease, nephritis and hypertension

Alan Morgan Davis, Portland Ore., University of Oregon Medical School, Portland, 1938, a first lieutenant in the medical reserve corps of the U S Army not on active duty aged 29, died, December 18, in San Francisco of Hodgkin's disease

Theodore Benjamin Davis, Newnan Ga. College of Physicians and Surgeons, Baltimore, 1881, aged 85, died recently

Wayland Whitten Deering, Shenandoah, Iowa, Eclectic Medical Institute, Cincinnati, 1898, aged 70, died recently of coronary thrombosis

Thomas Sewell Fuson, Cumberland Gap, Tenn., Hospital College of Medicine, Louisville, Ky, 1906, served during World War I, aged 65, died, February 13, as the result of a cerebral hemorrhage which occurred in September 1942

Henry Walter Gilley, Ottawa, Kan. Detroit Homeopathic Medical College, 1872, member of the Kansas Medical Society, served on the staff of the Ransom Memorial Hospital, aged 92, died, November 18

Thomas Edward Griffiths * Chicago Chicago Medical School, 1921, served with the Scottish Highlanders during the Boer War, physician for Armour and Company's Thirty-First Street Auxiliary, aged 57, died January 6, in St Luke's Hospital of acute coronary thrombosis

Lewis Scott Hay, Rock Hill, S C, Medical College of the State of South Carolina, Charleston, 1910, member of the South Carolina Medical Association, served as a first lieutenant in the U S Navy Air Corps during World War I, member of the staffs of the York County and St Philip's Mercy hospitals, aged 55, died, January 22, in the Veterans Administration Facility, Oteen, of pulmonary tuberculosis

Holm Holmson, Anaheim, Calif., Rush Medical College, Chicago, 1906, aged 69, died, December 24, in the Queen of Angels Hospital, Los Angeles, of internal hemorrhage as the result of an automobile accident

Julius Jungmann, New York, College of Physicians and Surgeons, New York, 1895, aged 90 died, December 31

Michael Bernard Kelly, Wheeling, W Va., College of Physicians and Surgeons, Baltimore, 1903, member of the West Virginia State Medical Association, fellow of the American College of Surgeons, past president of the Ohio County Medical Society, served on the staff of Wheeling Hospital, served during World War I, aged 70, died, December 10, in Charleston

Martin N Lehmayer, York Pa., Hahnemann Medical College and Hospital of Philadelphia, 1886, president of the Pennsylvania Tool and Manufacturing Company, formerly director of the Farmers Bank and Guardian Trust Company, aged 78, died, December 11

John Joseph Maney, Lawrence, Mass., Baltimore Medical College 1900, aged 67, died, December 11, in the Burke Memorial Hospital of chronic myocarditis

Robert Mann, Memphis, Tenn., Memphis Hospital Medical College, 1904 member of the Tennessee State Medical Association, on the staff of the Baptist Memorial Hospital, aged 62, died, January 1

Charles Bradford Mayberry, Wayne, Pa., Harvard Medical School, Boston, 1887, member of the Medical Society of the State of Pennsylvania and the American Psychiatric Association formerly physician in charge of the Hospital for Insane, Retreat, aged 80, died, December 27, in the Bryn Mawr (Pa) Hospital of pulmonary edema

Alexander Murray, Lord's Cove, N B, Canada, Jefferson Medical College of Philadelphia, 1892, Northwestern University Medical School, Chicago, 1893, aged 84, died in December

James T Musselman, Paris, Ill. Louisville (Ky) Medical College, 1879, member of the Illinois State Medical Society, past president of the Aesculapian Society of Wabash County for many years director of the First National Bank, surgeon for the New York Central Railroad for fifty-nine years a member of the first pension board of Edgar County, aged 88, died December 17

Harlan Forest Nelson, Brooken Minn., University of Minnesota Medical School, Minneapolis, 1935, aged 35, died December 6, in an automobile accident

John Adna Peterson, Hingham, Mass., University of Vermont College of Medicine, Burlington, 1896, formerly a medical examiner of the Fifth Plymouth District, aged 72, died, December 26

John Plunkett, Freeport, N Y. University of the City of New York Medical Department, New York, 1892 aged 82 died December 21

James R Priest, Houston, Miss., Memphis (Tenn) Hospital Medical College, 1903, member of the Mississippi State Medical Association, aged 65, died, December 5

Edmund Houghton Sawyer * Pasadena, Calif., Harvard Medical School, Boston 1908 aged 61, died recently in San Francisco of rheumatic heart disease

John Henry Stidham, Safford Ariz., College of Physicians and Surgeons, Little Rock 1910 served during World War I, aged 65, died, December 26, in the Morris-Squibb Hospital of injuries received in an automobile accident

Charles Samuel Strahan, Galesburg, Kan. (licensed in Kansas in 1908), aged 81, died, December 12, of heart disease

Albert E Swartz, Chicago, College of Physicians and Surgeons of Chicago, 1895, formerly a school doctor, aged 67, died, February 4, in the Wesley Memorial Hospital of lobar pneumonia and uremia

Charles Abram Van der Beek, Rochester, N Y., University of the City of New York Medical Department, New York, 1889, member of the Medical Society of the State of New York, aged 79, died, December 15, in the Genesee Hospital

Lilian Barbara M Yeomans, Manhattan Beach, Calif., University of Michigan Department of Medicine and Surgery, Ann Arbor, 1882, aged 81, died, December 9, of arteriosclerosis and heart block

DIED WHILE IN MILITARY SERVICE

Joseph Lewis Stettauer, Chicago, College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1901 member of the Illinois State Medical Society, commandant of the aviation cadet examining board at Winston-Salem, N C., began active service in February 1941 as a lieutenant colonel in the U S Army and was a medical inspector of the thirty-third division at Camp Forrest Tenn., at one time a captain of the 108th medical regiment of the thirty-third division of the Illinois National Guard, for two years served as chief of the staff of the Rotunda Lyng-In Hospital, Dublin, Ireland served on the staffs of the Jackson Park Hospital and St Luke's Hospital, where he died, January 3 while on a ten day leave, of acute coronary thrombosis, aged 60

Harry Charles Nash * University Heights, Ohio, Western Reserve University School of Medicine, Cleveland, 1922, had been senior assistant visiting surgeon at the St Vincent Charity Hospital Cleveland, began active duty as a captain in the medical corps of the United States Army Air Forces in September 1942, aged 45 stationed at Teague Texas, where he died January 3 of coronary disease

EVOLUTION OF OUR KNOWLEDGE OF TUBERCULOSIS

To the Editor—In an editorial in *THE JOURNAL*, Nov. 18, 1939 on the "Evolution of Our Knowledge of Tuberculosis" there appears the following. It is said that William Stark who was studying the pathology of phthisis in London under the renowned John Hunter died of tuberculosis as the result of a wound received in the morgue. Baillie the successor of Stark also developed an infection of the hand after performing a necropsy and died of tuberculosis but not until his years of study had clarified the knowledge of the tubercle.

I have been unable to find this story about William Stark, although I have consulted the Dictionary of National Biography, Smyth's Introduction to Stark's work 1788 and the account of his illness and death in the same volume. Also I am unable to find any connection between Baillie's infection of the hand from a slight wound while dissecting a putrid body and his death many years after of the "consumption."

Can you tell me where this information can be obtained? I have read a number of lives of Mathew Baillie including that of James Wardrop and find it hard to explain how Baillie, born in 1761 became Stark's successor. Stark having died in 1770 Mathew Baillie worked under William Hunter so that I am quite confused. Could you give me the sources for these observations?

W. L. HOLMAN, M.D., Toronto

COMMENT—The questions raised were sent to Dr. Lewis J. Moorman, on whose paper in the *Journal of the Oklahoma State Medical Association* of June 1939, page 204, the editorial was based.

The story about William Stark appears in Dr. Lawrence F. Flick's "Development of Our Knowledge of Tuberculosis" published by the Wickersham Printing Company, Lancaster, Pa. in 1925, p. 190. With reference to the statement that Mathew Baillie was Stark's successor may I call attention to the fact that in my original article I merely state that Mathew Baillie having recently graduated in medicine, received an appointment in St. George's Hospital to work in the autopsy room where Stark had received his fatal infection. No doubt Baillie was inspired by the work of young Stark and sought the opportunity of pursuing the latter's pathological researches under his famous uncle John Hunter. This does not necessarily imply that Baillie was Stark's immediate successor. Flick points out the fact that Baillie followed his postmortem studies at St. George's Hospital for eighteen years. John Hunter received his appointment at St. George's Hospital in 1768 and was on duty at St. George's when he died in 1793.

Referring to the question about Baillie's autopsy wound, I again quote from the original article which gave rise to the editorial. He [Baillie] also received an infection of the hand while performing an autopsy but died of advanced pulmonary tuberculosis at the age of 62. This may be misleading but the author did not mean to imply that the advanced tuberculosis had any relationship to the autopsy wound.

My information with reference to John Hunter and his brother William came chiefly from Benjamin Hutchinson's "Biographia Medica," published in 1799. Even though Baillie worked with William Hunter, it is my impression that he and Stark both pursued their pathologic studies under Dr. John Hunter.—Ed.

VACCINATION AGAINST SMALLPOX

To the Editor—During the recent outbreak of smallpox in Pennsylvania, mass prophylactic cowpox vaccination was begun in Philadelphia. I myself have had the unpleasant experience of having additional vaccinations on both thumbs, which are requiring surgical attention besides that self inoculated on my left arm. In view of this experience I think it advisable to offer the following suggestions to prevent such occurrences in other physicians who may be called on to carry out inoculations on a large scale.

1 Adhesive strip tapes on the tips of the fingers, particularly the thumb and index finger of both hands.

2 The use of full rubber gloves or finger cots, which are inexpensive. Should the rubber tear, additional protection will be had by the under covering adhesive tape. Rubber protection is advised in order to prevent alcoholic dehydration of the skin of the finger tips with subsequent fissuring, which renders accidental inoculation and secondary infection more likely.

3 The absolute mark filing of the glass enclosed vaccine and needle tubes. This is done in order to prevent glass splintering. Despite the fact that the biologic brochures advise only simple finger breaking of the glass tubes, the foregoing is advisable. Breaking of the glass tubes in gauze or cotton is an added precaution.

In addition, in order to save vaccine, two or three inoculations might be obtained from one tube. I might add that other physicians and assistants have had such occurrences and I trust that my experience will be of help in preventing these.

PHILIP R. TROMNER, M.D., Philadelphia

COOLING IN SHOCK

To the Editor—I was interested in the editorial on cooling in shock (*THE JOURNAL*, February 6, p. 432). My own thoughts have been similar to those which you express. I think you will be interested to hear of observations told me by a nurse with a British surgical unit in loyalist Spain during the war there. She said that they were up front in two heavy attacks, one in the mountains in the winter and one in the dry plains in the summer. Troops, diets and injuries were comparable. That the degree of shock, especially for lesser injuries, was so much greater in the summer fighting with repeated fatalities from minor wounds, was the subject of repeated and prolonged staff conferences, without reaching any conclusions. Under war conditions dehydration complicates the analysis of the effect of temperature alone. According to her description, the temperature contrasts were pronounced, as both cold and heat were intense.

University of California Medical School,
San Francisco

CONTINUOUS CAUDAL ANALGESIA IN OBSTETRICS

To the Editor—There has been misunderstanding regarding the cost of "continuous caudal anesthesia for painless childbirth" proposed by Hingson and Edwards. Comment by radio, magazine and newspaper reviewers contains the statement "Cost of the new method, it is estimated should average about \$3 per patient." This "cost" refers only to cost of materials and not average charge which will be made for the administration of continuous caudal anesthesia.

PAUL M. WOOD, M.D., New York
Secretary, American Society of Anesthetists

Council on Medical Education and Hospitals

CONTINUATION COURSES FOR PRACTICING PHYSICIANS

In accordance with the plan of the Council on Medical Education and Hospitals advance information concerning continuation courses for practicing physicians available in the various centers is published quarterly. The following list consists of courses beginning during the period April 1, 1943

June 30 1943. It is hoped that this material will be useful to physicians seeking opportunities for postgraduate work. Physicians called on to assume new responsibilities because of the war and physicians who are returning to practice may find here listed courses which will be of help to them. Since many of the classes are necessarily limited, those who contemplate enrolling in any of these courses are urged to communicate as early as possible with the proper executive officer.

H. G. WEISKOTTE, M.D.

Secretary, Council on Medical
Education and Hospitals

Continuation Courses for Practicing Physicians—April 1 1943–June 30, 1943

Institution	Schedule of Course	Title of Course	Number of Students Accepted	Registration Fee and/or Tuition
ALLERGY—See also Dermatology & Syphilology				
American College of Physicians 4700 Line Street Philadelphia Pa. Write to E. R. Loveland Executive Secretary	April 1943 2 weeks, full time	Allergy	Limited 10

MEDICOLEGAL ABSTRACTS

Dinitrophenol Blindness Attributed to Use of Drug
—Cecilia Wennerholm and her husband sued the Stanford University School of Medicine, the Stanford University Hospital, the Lane Hospital, the Board of Trustees of Leland Stanford Junior University and several individuals for damages for the loss of the wife's eyesight, purportedly due to the use by the wife of dinitrophenol, manufactured and distributed by one of the defendants, for relief from obesity. The original and first four amended complaints filed by the plaintiffs were framed on a theory of negligence. The defendants, it was charged in those complaints, caused articles to be published in medical journals and elsewhere to the effect that dinitrophenol was harmless. These statements were read and relied on by the plaintiffs and by the physician who attended the wife and prescribed the drug, and the defendants knew or should have known of the dangerous character of the drug but negligently failed to disclose that fact in the articles referred to. The plaintiffs abandoned the theory of negligence and filed a fifth amended complaint predicated on fraud alleging that (1) the defendants manufactured and distributed to retail outlets dinitrophenol, (2) the defendants falsely stated and represented in effect, in articles which were caused to be printed in newspapers, pamphlets, circulars and medical journals that dinitrophenol was a harmless drug which could be taken internally by human beings and would reduce excessive weight and alleviate obesity without causing physical harm, (3) as a matter of fact, the defendants well knew that dinitrophenol was poisonous and deleterious to the human body, was inherently dangerous to human life and limb and was liable to cause blindness, and (4) the wife, reading and relying on various statements caused to have been published by the defendants and being ignorant of the falsity of those statements to reduce obesity purchased and took internally amounts of dinitrophenol daily from March 9 to Dec 30, 1934 and by reason thereof became blind. The trial court sustained demurrers interposed by the defendants to the complaint and the plaintiffs appealed to the district court or appeals first district division I California

which affirmed the judgment of the trial court (*Wennerholm v. Stanford University School of Medicine*, 113 P. (2d) 736 (Calif., 1941), J. A. M. A. 119 903 [July 11] 1942). An appeal was then taken to the Supreme Court of California.

The sole question before the court was whether or not the fifth amended complaint stated a cause of action. If it did, the trial court was in error in sustaining the demurrers. The defendants contended that the complaint did not state a cause of action because it did not specifically allege that the false representations alleged to have been made were made with an intent to deceive the plaintiffs. The court believed, however, that the intent to deceive sufficiently appeared by the facts alleged in the complaint, from which it may be inferred that the alleged false statements were made with the intention of inducing the public to purchase the drug. One who intends to defraud the public, said the court, or a particular class of persons, is deemed to have intended to defraud every individual in the class who is actually misled. The court therefore concluded that while the complaint was somewhat martistically framed, it did state a cause of action for fraud.

The defendants next argued that the allegations in the earlier complaints that dinitrophenol had been taken on the prescription of a physician which allegation was omitted from the amended complaint under consideration, must be read in that complaint and that if such an allegation is read into the last complaint the complaint on its face will conclusively show that the plaintiff did not act in reliance on the representations of the defendants. Even granting, said the court that the allegation that the plaintiff took the drug on the advice of her physician must be read into the fifth amended complaint, that complaint sufficiently alleges reliance by the plaintiff on the defendants' representations. In actions for fraud it is not required that a defendant's representations be the sole cause of the damage. If they are a substantial factor in inducing the plaintiff to act, even though he also relies in part on the advice of others, reliance is sufficiently shown. In this case there was no allegation in the earlier complaints that the plaintiff relied solely on the advice of her physician, in fact it is alleged in the second amended complaint that "plaintiff and her said physician believed and accepted the recommendations of defendants and relied on the same and the said physician, in reliance thereon, prescribed for plaintiff, and the said plaintiff in reliance thereon and upon the advice of her physician, formed upon such recommendation of the defendants, used said dinitrophenol." In the fifth amended complaint it is alleged that the plaintiff "relying upon the aforesaid representations of said defendants, and not otherwise purchased and took internally" the said drug. Accepting this statement as qualified by the allegations with respect to the physician in the earlier complaints, it sufficiently alleges that plaintiff relied, at least in substantial part, on the representations of the defendants. The mere fact that a physician prescribed the drug does not establish, as a matter of law, a lack of reliance on the part of the plaintiff which would absolve the defendants from liability. The court did not regard as reasonable the contention advanced by the defendants that in circumstances such as those alleged here a prescribing physician must accept sole responsibility for the treatment which he chooses for his patients. It seems a more reasonable view to us, said the court, that one who manufactures and sells a drug dangerous to life and health, knowing it to be dangerous, should be liable where, as here alleged, both physician and patient rely on the representations made concerning the drug.

The defendants next contended, in support of the trial court's sustaining of the demurrers, that the cause of action is barred by the statute of limitations since the fifth amended complaint, charging fraud while the complaint and the first four amended complaints merely charged negligence, states a new and dif-

ferent cause of action from that alleged in the original complaint. Unless the amended complaint, answered the court, sets forth an entirely different cause of action from the original the amended complaint, for the purposes of the statute of limitations, must be deemed filed as of the date of the original complaint. The modern rule, when an amendment is sought after the statute of limitations has run, is that the amended complaint will be deemed filed as of the date of the original complaint so long as recovery is sought in each complaint on the same general set of facts. A mere change in legal theory will not subject the amended complaint to the bar of the statute of limitations. In the present case the only substantial difference between the factual situations set forth in the original and in the fifth amended complaint is that the former charged that the representations were negligently made while the latter charges that they were made with knowledge of their falsity. Despite the change in legal theory from an action for negligence to one for fraud, it cannot be said that an entirely different cause of action is stated. Therefore the fifth amended complaint, the one under discussion, is not barred by the statute of limitations.

The court accordingly reversed the judgment of the trial court sustaining the demurrers interposed by the defendants—*Wennerholm v. Stanford University School of Medicine*, 128 P. (2d) 522 (Calif. 1942).

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1932 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

Effect of Kidney Extracts on Blood Pressure—Schales, Stead and Warren injected intramuscularly prepared kidney extracts into the buttocks of 7 patients with arterial hypertension. The patients were hospitalized but were ambulatory throughout their hospitalization. The blood pressure was determined twice a day and the temperature was recorded at least four times a day. The severity of the local reactions was graded from 1 to 4 plus, depending on the amount of induration, erythema and tenderness. Roentgen examination of the heart, electrocardiograms and blood and urine studies were obtained at various times throughout the hospitalization. Four of the 7 patients had malignant hypertension and 3 had a more chronic or benign variety. Of the 2 male patients, both with malignant hypertension, treated for two and three weeks the blood pressure did not show a significant variation nor was there any definite symptomatic change. Only minimal soreness and induration at the site of injection occurred. In the remaining 5 female patients the daily intramuscular injection of kidney extract produced a significant decline in arterial pressure. The initial injections were followed by slight tenderness and pain at the site of injection, but after two to ten days a more severe type of reaction occurred. Several hours after injection the site was surrounded by an area of pronounced induration, which usually involved the entire buttock and frequently spread over the sacral and lumbar regions. The skin was red and hot, and often an erythematous confluent macular eruption occurred, which involved not only the skin of the injected buttock but also the skin of the sacrum and the lateral and anterior aspects of the thigh parallel to and just below the inguinal ligament. Associated with this severe local reaction there were various constitutional symptoms of fever, chills, sweating, anorexia and lethargy. A significant lowering of the arterial pressure appeared to be related to the fever, sweating, weakness, anorexia and severe local reactions. Injection of extracts poor in hypertensinase produced a fall in arterial pressure similar to that produced by the unmodified extract. The conclusion is that the decrease in arterial pressure was produced by a nonspecific effect of the renal extracts on the body rather than by specific interference with a renin-hypertensin system.

Biotin Metabolism in Man—In his study of the excretion of biotin in the urine of man, Oppel found that normal subjects on unrestricted diets excreted from 7 to 89 micrograms of biotin (as measured by yeast growth stimulation) per liter of urine.

With ordinary diets the biotin elimination varied daily and throughout the day. There was a striking increase immediately after a large dose of crude biotin was ingested. The biotin excreted in the urine of those who ate well was greater than of those whose intake of food was poor. It was relatively constant for those who ate the same food every day. The biotin excretion of patients with various diseases showed the values to be within the normal range and even during periods of starvation the excretion was not abnormally low. A study of a small group of hospital patients on diets of known biotin content revealed that if the daily biotin intake was constant the biotin excretion also was constant for each subject. When diets containing 35 and 65 micrograms of biotin were taken on alternate days, the urine showed corresponding daily fluctuations. The average daily biotin content of the feces appreciably exceeded the biotin content of the diet. The total biotin output in the urine and the feces was three to six times as much as the dietary intake. The material in the urine which gives the biotin test by the yeast growth assay can be separated into an avidin combining and a non-avidin combining fraction, both fractions have been found in the urines of the human being, dog, rabbit and rat. The avidin combining fraction is probably biotin. Its excretion in the urine varies with the amount of biotin in the diet. Small amounts of it were excreted by patients taking diets containing large amounts of egg white and none in the urines of 2 biotin deficient rats. The non-avidin combining fraction has been found in all urine tested and its quantity was not changed by the biotin content of the food or by oral doses of biotin. Only minute amounts of the non-avidin combining fraction were found in diets and feces.

Unfavorable Sequelae After Injection of Contrast Mediums—The death of a patient following the intravenous administration of 3,5 diiodo 4 pyridone-N-acetic acid and diethanolamine (diodrast) for a urographic study prompted Pendergrass and his associates to send questionnaires to radiologists and urologists. The latter returned information on 220,000 urograms and the former on 441,800. An analysis of the data showed that there were 26 deaths in addition to the 11 already reported in the literature. Ten deaths were immediate, the result of hypersensitivity or idiosyncrasy to the drug injected or to colloidal shock, and 16 deaths were delayed, presumably because of preexisting major renal damage. All immediate deaths were of patients who had received diodrast and were preceded by symptoms of anaphylactic shock, although they may not have been due to an "anaphylactoid reaction." Overdosage may have been the cause. The contrast medium in the delayed deaths had not been proved to be an etiologic factor. Toxic reactions may occur especially in patients with previous renal damage and urea reduction. No immediate deaths have been reported following retrograde pyelography with contrast mediums. Instances of nonfatal hypersensitivity, simulating anaphylactic shock, have occurred following the intravenous use of contrast mediums. Contrast mediums are contraindicated.

cated in patients with severe hepatic disorders, nephritis, exudative diathesis (in children), allergy and severe uremia. They should be used with caution in pulmonary tuberculosis, hyperthyroidism, in patients in whom a reduction of blood pressure would be dangerous and in patients who have had repeated injections of contrast mediums. To prevent anaphylactic reactions the oral, intravenous, intradermal and conjunctival tests are helpful. However, their use will not warn adequately against the toxic reaction. Therefore, with the increased use of contrast mediums, radiologists and physicians should be on the alert so that its use, which has permitted such great advances in diagnosis, and its users will not fall into disrepute.

Test for Contrast Medium Sensitivity—Archer and Harris outline an ocular test for discovering a patient's sensitivity to diodrast. The test is accurate, quick and simple and has been used in more than 600 cases, sometimes even in the face of historical contraindications such as allergy, hypertension, previously administered sulfonamides and iodides. The eyes are examined for comparison and a drop of the dye is placed directly on the conjunctiva of one eye. The patient closes his eyes as in sleep for one and a half minutes after which the eyes are examined (daylight is preferable) and then again two minutes later. The reacting eye is compared with the control. The injection of the vessels of the sclera and conjunctiva is the criterion of the test. The reactions are divided into minimal, moderate and decided types. In a minimal reaction the dye may have no effect, or the patient states that he has a hot flash and some nausea. Patients with moderate injection react to intravenous injection with nausea, vomiting, vasomotor dilatation and occasionally generalized pruritus, urticaria and some slight swelling of the membranes of the upper part of the respiratory tract. The reactions are temporary with no sequelae. In decided injection the vessels are engorged from the iris to the periphery. This absolutely contraindicates the intravenous use of the dye. These dangerous reactions have included vasomotor and respiratory collapse, laryngeal edema, severe asthma, generalized urticaria, pruritus and even (delayed) dermatitis. As some patients complain of temporary burning in the tested eye they should be forewarned so that they will not rub the eye, thus producing a false positive reaction. The reaction in the muddy sclera of Negroes is harder to read, but a unilateral difference is readily discernible. There should be no alcohol on or in the needle of the syringe, as with the dye it causes a decided reaction.

Bacteriostatic Compounds in Otolaryngology—The experience that Bordley and his colleagues have had with bacteriostatic agents indicates that many of the complications of secondary infections of the sinuses, ears and lymphoid tissue and much of the discomfort of acute coryza or nasopharyngitis may be prevented by spraying the nasal passages and pharynx with a 2.5 per cent sulfadiazine triethanolamine solution at least eight times a day during the first two days and five or six times a day for the next two or three days. The results of a rigidly controlled experiment in 30 student nurses who reported for treatment in an average of twenty-four hours after onset of acute coryza or nasopharyngitis show the spray to be most efficacious. Without their knowledge the nose, nasopharynx and pharynx of alternate patients were sprayed with the solvent (triethanolamine) and of the others with the solvent plus 2.5 per

cent sulfadiazine. Two of the 16 treated patients had slight clouding of one antrum on transillumination, which cleared without local treatment, while in the control group 7 of 14 patients had complicating infection of accessory nasal sinuses. One patient had had acute sinusitis with each cold during the past four years, and six such attacks during the previous winter required irrigation of an antrum. During the past winter the absence of sinus infection was attributed to the use of the sulfadiazine spray. Gramicidin was most valuable when used to supplement surgical operation. Postoperative fever, swelling, pain and irrigation or frequent dressings may all be prevented by painting the entire operative area with gramicidin and packing the wound with gauze saturated with gramicidin. This result is obtained only when the infecting organisms are sensitive aerobic or anaerobic streptococci or some type of pneumococci. The strength of the gramicidin suspension must not exceed 1 mg. per cubic centimeter. Sterile penicillin (the filtrate) is suitable for local application in infected wounds and for irrigation of the middle ear or accessory nasal sinuses. Penicillin is superior to gramicidin in that it is soluble in water, penetrates tissues and is neither toxic nor irritating to mucous membranes. It is especially effective for staphylococci and bactericidal for aerobic and anaerobic streptococci and pneumococci. As with gramicidin, certain strains of these organisms may be resistant. Therefore their intelligent use necessitates careful bacteriologic study of each patient.

Effect of Androgen Therapy on the Voice of Women—According to Goldman and Salmon in 23 of more than 400 patients receiving androgen therapy for various endocrinopathic gynecologic disorders, symptoms of hoarseness, huskiness and masculine pitch associated with structural alterations of the vocal cords were observed. The vocal cords, on indirect mirror laryngoscopy, showed a characteristic picture of generalized suffused swelling with injected blood vessels. A pile off-white color with caudal extension of the swelling making the subglottic surfaces of the cords visible, was a consistent laryngeal feature. The vocal disturbance and physical alterations persisted for varying periods, up to two and a half years after androgen therapy was withdrawn in 11 cases. The study suggests that there is a striking similarity between the vocal and laryngeal changes in women who receive androgen therapy and the physiologic development of the voice and larynx in boys at puberty. To avoid the changes in women receiving androgen therapy the dose must be kept below the threshold for these phenomena. For the average woman this threshold is approximately 500 mg. of testosterone propionate per month. As an additional safeguard against androgen overdosage is the taking of weekly vaginal smears and the discontinuance of therapy if the effects of androgen appear in the smear.

Treatment of Burns with Chemotherapeutic Membranes—Andrus and his associates used preformed hydrated chemotherapeutic membranes (eschars) in the treatment of second degree burns of 10 patients. The membranes contained 10 per cent sulfanilamide and buffer, with and without azo chloramid. If after their application excessive oozing threatens to disintegrate the film a second or third layer can be applied over the first. Also by mounting these films on gauze they can be made into sheets large enough to encircle the torso of an adult. The longest elapsed time required for complete healing

(return to work) was twenty-one days, this was in a case in which extensive burn about the head involved all the hair and eyebrows. The following technic was used. The burn was first debrided and thoroughly cleansed with saline boric acid or azochloranid solution. All dead skin was removed and the preformed membrane was applied directly to the raw oozing surface. A dry sterile dressing was placed over the membrane and held by a plain gauze bandage. Given a large number of burns (on board ship for instance) the membrane can be applied quickly and easily by any one trained in first aid and can be held in position by the dry dressing. If its removal is necessary it is moistened with sterile water or saline solution. Since submitting their paper the authors have treated 10 additional patients who had severe second degree burns, their average healing time was nine days. The burn of 1 patient involved 55 and of 1 patient 35 per cent of the surface of the body. Healing in both was complete in twelve days.

Pulmonary Embolism—Potts and Smith studied the value of exercise in lessening the incidence of pulmonary thrombosis. Their material consists of 837 private patients who have carried out the exercises the evening of the operation and each morning and evening thereafter and a control group of 124 patients with fractures which required immobilization and 150 surgical patients who did not carry out the postoperative exercises. The exercises consisted of fifteen deep breaths and active flexing of the legs with each breath. There has been no phlebothrombosis or pulmonary embolism among the 837 private patients. In the first control group there were 5 instances of phlebothrombosis, 4 were followed by pulmonary infarction, and pulmonary embolism was found in 1 at postmortem examination. The origin of the emboli could not be found. Among the surgical control group 4 patients had phlebothrombosis, in 2 the thrombosis followed drainage of an appendical abscess, in 1 the release of a mechanical intestinal obstruction and in 1 the abdominoperineal resection of the rectum. Experimentally the authors have produced thrombosis in the femoral vein of a dog after double partial ligation.

Studies of Gramicidin, Tyrothricin and Tyrocidine—In their in vitro and in vivo studies of the bactericidal activity of gramicidin, tyrothricin and tyrocidine Robinson and Graessle found that the last two appear to exert a decided bactericidal action on aerobic and anaerobic gram positive bacteria in the absence of blood or serum, under similar conditions gramicidin appears to be primarily bacteriostatic. When blood or serum is present tyrocidine and tyrothricin lose their bactericidal properties whereas gramicidin retains its bacteriostatic properties,

under these conditions tyrothricin becomes primarily bacteriostatic. In vivo results indicate that gramicidin and tyrothricin intraperitoneally in infected mice are active whereas tyrocidine is not. Gramicidin or tyrothricin are effective only when given in direct contact with the infecting bacteria. Oral, subcutaneous or intravenous treatment did not protect mice infected peritoneally. Likewise, mice infected by vein were not protected by intraperitoneal treatment.

Distribution and Excretion of Gold in Arthritis—Following the intramuscular injection into the white rat of oily suspensions of gold calcium thiomalate and gold thioglucose Block and his associates found the rate of absorption of the gold to be somewhat faster in the case of the latter compound. Larger amounts of gold were present in the kidneys and liver than in other tissue studied. Excretion occurred through the kidneys and the gastrointestinal tract. The chief route of excretion of the soluble gold thioglucose was the kidneys while gold was excreted primarily in the feces following the administration of the insoluble gold calcium thiomalate.

Castration for Carcinoma of Prostate—Aljca and Henderson discuss the immediate response to castration of 40 patients with carcinoma of the prostate. The procedure was carried out on all during the past year. Contact was made with all but 1 for this first follow-up, 4 died (1 one day postoperatively from shock, 1 one month postoperatively from cerebral hemorrhage and 1, the 1 unsatisfactory case, recently from carcinomatosis), 30 returned to the clinic for reexamination and 5 answered the authors' questionnaire by mail. The early results show that their general improvement was astounding. All claimed to feel better than they had in years with decided improvement in appetite, energy and well being. The only adverse results have been the loss of libido and potentia in all but 1 and hot flashes in 3. The hot flashes have been controlled by small doses of diethylstilbestrol for three to five days at a time. The relief of pain from metastasis was most remarkable. In 1, such pain with extension of the disease returned after eight months of comfort. Changes in the primary growth following castration were evident clinically and at necropsy. Roentgenograms show the healing of bone in metastatic areas after castration and in 4 in disappearance of a metastatic tumor in the lungs after castration.

Treatment of Carcinoma of Prostate—In treating their last 27 cases of inoperable carcinoma of the prostate Clute, Willetts and Gens employed castration, estrogen or a combination of the two in 21. Clinically only 1 patient was not decidedly benefited by the treatment. In a few cases the improvement almost suggested cure. The most immediate and striking effect was rapid relief from severe pain due to metastasis, if present, and then great improvement in appetite and general health with gain in weight and a reduction in the size and induration of the prostate with an improvement in the ability to urinate. The quickest and most satisfactory results were obtained by castration followed by the injection of 10 mg of diethylstilbestrol a day for five to ten days. After castration, libido and the power of erection usually disappeared; there were no other harmful effects. No beneficial effect was observed on bony metastasis. Roentgenograms taken over a period of more than six months showed apparent progress as usual.

Castration for Cancer of Prostate—Randall presents the histories of 5 patients with carcinoma of the prostate who were castrated seven, eight and nine years ago in the hope of influencing their inoperable carcinoma. Of these patients none were cured of the malignant process. Urinary obstruction, in addition to the malignant process, was present in all. The microscopic sections in the 4 patients who have since died have been reviewed and the diagnosis has been reaffirmed. It has been especially difficult to trace any record of clinical benefit. They lived respectively for seventeen months, three and a half years, forty-three days and eight months. In 2 at least there was definite clinical improvement, but this the author believed was due probably as much to the prostatic resection as to the castration. The one living patient is now 70 and was castrated six and a half years ago. Now his referring physician writes that the patient was in good health, free from pain or urinary difficulty until April 1941, when he complained of pain in the lower part of his back and of pain of the right hip and the inability to move his right leg. Roentgen examination revealed massive metastasis of the dorsolumbar spine. Three courses of epidural and subdural procaine injections relieved all pain, with eventual recovery of the function of the right leg. After the use of diethylstilbestrol and several courses of roentgen therapy to the prostate the patient is now free from all pain and voids well enough to dispense with a catheter. The prostate is hard and of relatively normal size. His appetite is good, his weight is constant and his general condition is good. The author points out that he does not present these cases as an argument against the trend of present day therapy but only as an experience of several years standing that stands as a fact and should be recorded before a wave of enthusiasm (and of castration) passes over this country.

Immune Serum for Leptospira Icterohemorrhagiae in Mice—Larson tested the value of specific immune leptospirosis serum and the concentrated fraction of this serum in the treatment of groups of 24 mice infected with Weil's disease. The materials were given one, three, five and six days after infection. Both materials were effective when administered on the third day of infection, only about 50 per cent of the animals survived when treatment was instituted on the fifth day and none survived if serum was withheld until the sixth day. As a control, 0.3 cc of normal rabbit serum was administered intra-

peritoneally to 24 infected mice twenty-four hours after infection had been induced. All but 1 of the animals died and presented typical signs and symptoms of leptospirosis. The method of determining the efficacy of the material included titration of the infective agent, titration of the specific protective antibodies in the specimen of serum or plasma tested and their inoculation into infected mice.

Herpes Simplex Virus in Spinal Fluid in Lymphocytic Choriomeningitis—Armstrong reports the isolation of a strain of herpes simplex virus from the spinal fluid of a Negro of 15 suspected of having lymphocytic choriomeningitis. Blood drawn during the attack did not protect mice against herpes infection, while a sample drawn after recovery had protective properties. Demonstrable antibodies against choriomeningitis were absent from all samples tested. The evidence suggests that herpes simplex virus may in rare instances be the causative agent of some aseptic or lymphocytic meningitis for which the cause is otherwise undeterminable.

Feline Virus and Atypical Human Pneumonia—Blake and his collaborators record the occurrence of an illness on Nov. 7, 1941 in a young farmer which resembled primary atypical pneumonia of the type which has been increasingly prevalent since 1934. The history revealed not only that 2 other members of the household had recently had a similar illness and that 1 was sick at present but also that 8 of 12 cats on the farm had died of a respiratory disease during October and that 2 of the remaining 4 cats were sick with the same illness. The possibility that the afflicted members of the family and the cats were infected with the same agent suggested itself and an attempt to isolate an etiologic agent by transmission experiments in cats and mice was carried out. A virus capable of producing a similar pneumonia in cats was recovered from the lungs of 1 of the cats. Kittens appeared to be more susceptible to the virus than were full grown cats. The virus failed to infect mice and therefore appears to differ from most viruses causing infections of the respiratory tract. The evidence so far obtained suggests, but does not establish, the fact that the respiratory infection in the patients may have been caused by the virus causing the illness in the cats.

Electroencephalographic Studies in Epilepsy—In the course of obtaining 4,500 electroencephalographic tracings of patients with a wide variety of neuropsychiatric disorders, Finley and Dynes were impressed by the variation of abnormal patterns within any given clinical group and by the similarity of many patterns in many diverse clinical disorders. An analysis of the electroencephalograms of 626 unselected epileptic patients shows that 86 per cent of the tracings were borderline or abnormal and 14 per cent were normal. Many of the patterns obtained from these patients were also found in other neuropsychiatric conditions. The spike and wave patterns usually furnished by epileptic patients occurred in less than 10 per cent. Less than half of these spike and wave patterns were from patients with petit mal epilepsy. Because of the foregoing, the use of clinical terminology in describing the brain wave patterns of epileptic patients is misleading. The electroencephalogram can continue to be of practical value to the neuropsychiatrist in the diagnosis of epilepsy if used as an adjunct to other laboratory data, the history and the clinical signs and changes.

Abdominal Surgery of "Total War"—Gordon-Taylor reviews the six hundred operations on the abdomen for injuries that he has encountered after more than two and a half years of conflict. The series includes abdominal injuries received in naval warfare, civilians damaged by air bombardment and certain army casualties from the flotsam and jetsam of the "Dunkirk miracle" and the evacuation of northern France, and others from the Royal Air Force who were brought down during the epochal "Battle of Britain." These cases, representing various types of injury from numerous missiles, have been collected haphazardly and afford no criterion for estimating the percentage of the total abdominal casualties for which surgery can be profitably employed. Despite the gravity of the wounds and the frequent association of multiple injuries, approximately 50 per cent of the patients with abdominal injury for whom

operation was possible survived. The present military situation permits of no information as to the percentage of these casualties for which operation has been possible. The percentage of recoveries for injuries to the stomach, the small intestine, the rectum and the spleen is higher than in 1914-1918, the recovery rate for injuries to the large intestine is the same. Few patients with extensive intestinal resections have survived; the successful cases have been mainly dealt with by suture. Exteriorization resections of the large intestine have not figured prominently among successful resections of the colon. The employment of the sulfonamides, locally and orally, has proved of inestimable value. The liberal transfusion of blood or blood derivatives has permitted operation on a host of patients who would otherwise have died. The abdominal surgery of 'total war' is really successful.

Nonpenetrating Injuries of Abdomen—O'Callaghan reports 2 instances of nonpenetrating injuries of the abdomen with visceral damage that occurred in civil life but that are not unlike those that can and do occur under wartime conditions. The injury in 1 was retroperitoneal rupture of the duodenum associated with laceration of the liver. The other patient had a laceration of the pancreas with tearing of the splenic vein. Both recovered following operation. In these patients shock was hardly evident at first but became serious following operation. Postoperative shock may be the serious danger; this was stressed by Mullally. Nonpenetrating injury to the abdomen may be produced in one of several ways: by impaling viscera against the bony structures of the body, by crushing of viscera against the vertebral bodies by puncture of viscera by fragments of fractured bone and complete rupture of the stomach when it is full at the time of the accident. Most authors accord a poor prognosis to these cases and blame the high mortality to errors in diagnosis and the inability to control associated shock. Most of the prognostic conclusions are based on results of some twenty to thirty years ago and therefore do not consider the effect of modern antishock treatment.

Etiology and Treatment of Duodenal Ulcer—After an experience of twenty years with some 4,000 operative cases of gastric and duodenal ulcer, Somervell believes that the operative treatment of duodenal ulcer should be stabilized on a firm and scientific basis, especially in India with its poor class of patient "whose stomach must be fitted for curry and rice in the shortest possible time," which depends largely on objective data and less on the personal opinion of the surgeon than has heretofore been the case. The effect of vitamin deficiency on the cause of duodenal ulceration is discussed by him and his belief is that deficiency of vitamins A and B₁₂ is the main dietetic cause of this condition in South India and possibly elsewhere. Roentgen examination and the fractional test meal, if operation is decided on, enable the surgeon to have a good idea before the abdomen is opened as to the best type of operation to perform. The advantages of ligation of gastric arteries in place of gastrectomy are set forward. Rapid reduction in gastric acidity is obtained by the ligation of a sufficient number of the arteries of the gastric wall. This enables the simple gastroenterostomy to be done instead of the more serious gastrectomy preferred by many surgeons in the past. Gastrojejunal ulcer is perhaps the most serious of all late sequelae of gastroenterostomy. Its treatment depends on the acidity, the general condition of the patient and the liability to recurrent ulceration as shown by the presence of more than one ulcer. Considering these three items, the best operation for any particular case can be decided soon after the abdomen is opened.

Gastroscopic Observations After Abdominal Operations Internal Condition of Stomach After Cholecystectomy L von Friedrich—p 132

*Intestinal Autointoxication as Cause of Chronic Blepharoconjunctivitis V L Szerdahelyi—p 147

Gastroscopic Observations in Anacidity—Christiansen reports results obtained by gastroscopy in 52 cases of histamine refractory achylia. All presented a normal roentgenologic picture. Gastroscopy disclosed a normal mucosa in 12 cases, superficial gastritis in 15, atrophic gastritis in 15, hypertrophic gastritis in 7, single erosion in 2 and complete atrophy in 1. These observations suggest that gastritis is the most common lesion in achylia. A considerable number of cases of achylia exhibit no anatomic signs of anacidity. Complete atrophy is rare. The condition of the gastric mucosa in anacidity, with the exception of total atrophy, is identical with that found in the presence of normal or increased acidity. In order to ascertain a possible relationship between the clinical symptoms and the condition of the mucosa in anacidity the cases were divided into 3 groups. In the first group, of 12 cases, dyspepsia was absent. In the second group, comprising 23 cases atypical dyspepsia was present. In the third group, of 17 cases, there existed a true pyloric syndrome. In groups 1 and 2 both normal mucosa and gastritis were found, in group 3 no normal mucosa was found, but only gastritis. The incidence of gastritis in anacidity seems to run parallel with the intensification of the clinical symptoms.

Intestinal Autointoxication as Cause of Chronic Blepharoconjunctivitis—Szerdahelyi cites reports from the literature which suggest that intoxication of intestinal origin plays a pathogenic role in many general symptoms and in disorders of the type of uremia, liver cirrhosis, pernicious and other anemias, ileus, chronic dysentery, chronic arthritis, many forms of neuritis, vasomotor rhinopathia, certain allergic manifestations, eczemas, bronchial asthma and the like. The author's patient had a chronic mucous colitis and chronic blepharoconjunctivitis. Intestinal intoxication was probably responsible for both, because the eye symptoms improved or got worse simultaneously with the intestinal disorder. Vaccination with lactose nonfermenting bacteria of the patient's intestinal flora cured the intestinal disorder and the blepharoconjunctivitis.

*Heart Disease Electrocardiographic Prognosis J Almela Guillen—p 356

Therapy of Hypogalactia by Combined Action of Blood and Urine of Pregnant Women J Uranga Goitia—p 372

Heart Disease—Almela Guillen discusses the prognostic value of the electrocardiogram in heart disease. Sinus arrhythmia, sinus bradycardia and sinus tachycardia are signs of an angioneurotic, vagotonic and vasolabile constitution respectively. These changes are of no pathologic significance. Extrasystoles which appear in the course of infections indicate myocardial infection. Auricular extrasystoles suggest myocardial damage. They appear frequently before a total arrhythmia. Ventricular extrasystoles are frequent in various diseases other than heart disease and in various physiologic states such as pregnancy. Extrasystoles which appear early in the administration of digitalis indicate acute myocardial lesions and contraindicate further administration of the drug. Extrasystoles with multiple foci of origin indicate myocardial lesions. Electrocardiograms with recurring alterations (Gallavardin's sign of alarm) indicate grave heart disease. Changes in the electrocardiograms of nervous youths and in persons who smoke excessively show functional disorders of the heart. Paroxysmal supraventricular tachycardia is of no pathologic significance whereas ventricular tachycardia is grave. It is frequently followed by fatal ven-

tricular fibrillation. Paroxysmal tachycardia in persons over 50 years of age indicates myocardial degeneration. The changes in the electrocardiogram which show auriculoventricular dissociation, elongation of the PQ segment in the acute period of an infection, the thickening and hooks in the main wave of the ventricular complex, changes showing bundle branch block, especially the auriculoventricular block, lowering of the ST segment below the isoelectric line and the inversion of the T wave are of grave prognosis. A low voltage of progressive lowering indicates diminution of the myocardial energy. The changes of the Q wave, especially in the third lead, are of prognostic significance when they are associated with other changes in the electrocardiogram showing myocardial infarct, coronary sclerosis, pericarditis or alterations in acute articular rheumatism. Electrocardiograms of patients with angina pectoris and with myocardial infarct are typical and of diagnostic rather than of prognostic significance. However, when the typical electrocardiograms of angina pectoris and of myocardial infarct show changes due to extrasystoles of multiple foci or a QS space of normal wideness, the prognosis is grave.

Allergy to Catgut and Adhesions—Vaccaro and Cabezas V investigated the capacity of catgut to sensitize animals and human subjects, its specificity relations with other organic materials, its absorption in the tissues, the development of aseptic inflammatory processes and the production of the Arthus phenomenon. They were able to demonstrate the antigenic and sensitizing character of catgut. Allergy to catgut appears regularly in guinea pigs and rabbits that have undergone preparative treatment with this material. The intradermal reaction to the antigen catgut becomes positive from four to eight weeks after the preparative cutaneous or peritoneal injection. In animals sensitized to horse or sheep serum or to human serum the intradermal reaction to catgut is persistently negative. Absorption experiments in nonsensitized animals proved the total absorption of peritoneally introduced catgut without late peritoneal reactions, nodules and adhesions. Animals sensitized to catgut show the Arthus phenomenon by aseptic inflammation, production of fibrous nodules, adhesions and chiefly by osseous degeneration. Catgut introduced into the peritoneum of rabbits sensitized with either horse or sheep serum is only partially and slowly absorbed, and late peritoneal reactions develop in the form of nodules and adhesions. In animals in which the cutaneous Arthus phenomenon has been produced with sheep serum and which have also been allergized to catgut, the absorption of catgut is extremely slow or negative and is accompanied by severe peritoneal inflammation and by adhesions. In non-allergic persons who have not been operated on, intradermal reaction gave 5 per cent of positive results to meat and to serum of sheep and 3 per cent to extract of catgut. The positive intradermal reactions increase progressively when the test is made on allergic persons, on those operated on and on those who have a history of allergy and of surgical intervention. Persons with cutaneous sensitivity to extract of meat or serum of sheep may have no allergy to catgut but sensitivity to catgut is found always in persons with positive reactions to the other antigens mentioned. In persons without a history of surgical interventions it is possible to interpret positive intradermal reactions to catgut as a sensitivity acquired by the digestive tract to the meat of sheep because the two antigens have a common origin. The authors recommend preoperative tests for sensitivity to catgut and replacement of catgut by nonabsorbable suture materials without antigenic properties.

Gas Warfare A Monograph for Instructors Compiled by W. K. Fitch
Published by the Pharmaceutical Society of Great Britain Paper Price
2s. 6d. Pp. 103 London Pharmaceutical Press 1942

This booklet represents an attempt to give a brief but well balanced survey of the whole field of gas warfare within the limits of a hundred small but closely printed pages. It is described as "a monograph for instructors" in the civilian defense and other similar organizations. One of its main purposes (as stated in the preface) is to give to the instructor a background which will enable him to "get the trainee to view the gas menace through the eyes of the chemist as something that need arouse no anxiety." With this purpose the reviewer is most heartily in sympathy. And the booklet is, on the whole, well designed to attain the object in view. It is well seasoned with interesting historical details, and the distribution of emphasis is on the whole just (one chapter devoted to tactics, seven chapters devoted to defense). The twenty page chapter entitled "General Properties of War Gases" is much too detailed. No less than twenty five toxic agents, some of them completely obsolete, are discussed at length. Ten would have been ample. Some of the data given are, moreover, inaccurate. The booklet may be recommended not only to the instructors for whom it is intended but to any one with a rudimentary scientific training who wishes to acquaint himself, by two or three hours of reading, with the general subject of gas warfare. The reviewer is not sufficiently well acquainted with other publications of the same nature to venture on a comparison.

Fundamentals of Immunology By William C. Boyd Ph.D. Associate Professor of Biochemistry Boston University School of Medicine Boston
Cloth Price \$5.50 Pp. 446 with 45 illustrations New York Interscience Publishers Inc. 1943

The purpose of this book is "to serve as introduction to immunology for medical students, chemists, biologists and others interested in an understanding of the basic principles of the science." The chapter headings will show the scope and plan of the contents: immunity and immunology, antibodies and antibody specificity, antigens, blood groups, antibody-antigen reactions, complement and complement fixation, anaphylaxis and allergy, allergy and immunity (bacteria, viruses, parasites), practical use of artificial immunity, laboratory and clinical technique. At the end of each chapter are references to "the latest and most pertinent literature." The last chapter, the longest, deals with immunologic methods and their application to certain diseases. The emphasis in the earlier chapter is on the basic principles as presented from the point of view of the chemist. It is assumed "that the reader has a slight previous acquaintance with organic chemistry and bacteriology." More than a slight acquaintance with chemistry would be needed to understand the discussion of conjugated antigens, the influence of optical activity and the preparation of synthetic antigens. The book meets its general purpose well but may be better suited for the chemist and the investigator than for the medical student, especially now when the medical course is shortened.

The Application of Absorption Spectra to the Study of Vitamins Hormones and Coenzymes By R. A. Morton D.Sc. Ph.D. F.I.C. Department of Chemistry The University of Liverpool Second edition Cloth Price \$6.50 Pp. 226 with 82 illustrations Boston Jarrell Ash Co. London Adam Hilger Ltd. 1942

The value of absorption spectroscopy in the isolation of natural products and the determination of their chemical structure is well illustrated by this timely revision of a useful volume the first edition of which appeared in 1935. The increased size and scope of the present book is an index of the tremendous advances which have occurred in the application of absorption spectrum data to the elucidation of the structure of complex molecules. The style of the first edition has been retained. Each section is a chronological treatment of the detection, concentration, isolation, structural determination and, in many cases, synthesis of a particular natural product, with the emphasis on the part played by absorption spectrums in each stage of progress. Thus the volume not only provides spec-

troscopic data for the various subjects presented but is, in addition, an excellent summary of our present knowledge of the topics discussed. Numerous references to the original literature and tables of spectrums with accompanying structural formulas are provided throughout.

A brief introductory chapter discusses the standardization of spectrometric apparatus provides a definition of the notation used in the following chapters and includes a bibliography of recent books and review articles on spectrophotometry. The chapter on steroids, provitamins and vitamin D and hormones has been greatly expanded and provides an excellent survey of structural determinations in this field. Since the first edition appeared, the chemistry of provitamins and vitamin A has been elucidated, a comprehensive review of this progress is now included. The status of spectrographic determinations of vitamin A is discussed as are the results of collaborative studies in this field. The chemistry and spectrums of vitamin E are clearly stated, and the subject of antioxidants which is of current interest is discussed briefly. Chapters on vitamin K, vitamin P, vitamin B complex, purine and pyrimidine derivatives, proteins and enzymes and coenzymes represent additions not present in the first edition.

The volume should be highly useful to the worker who may be called on occasionally to make use of absorption spectrum data, as well as to the trained spectroscopist.

Obstetrical Practice By Alfred C. Beck M.D. Professor of Obstetrics and Gynecology Long Island College of Medicine Brooklyn Third edition Cloth Price \$7 Pp. 938 with 1064 illustrations Baltimore Williams & Wilkins Company 1942

The appearance of a third edition of this book in seven years is an indication that it is popular. The new edition contains eighty more pages and twenty three more illustrations than the second edition. There are five more chapters in the new book, but this is because the author separated the material on operative obstetrics into six chapters. Many illustrations have been redrawn, and most of those in the section on operative obstetrics have been enriched by the addition of color. However the reproductions of roentgenograms are so poor that they should not have been printed.

Throughout this edition, as in the previous two, there is abundant evidence of the author's extraordinary ability as an obstetrician and as a teacher. In view of Beck's contribution to the technique of the low cervical cesarean section this operation is described and illustrated in great detail. Furthermore the details of the use of local anesthesia for this operation are given.

It is surprising and perhaps unfortunate that the author did not see fit even to mention the classification of the toxemias of pregnancy advocated by the committee appointed by the American Committee on Maternal Health. One of the purposes of this classification was to have a standard by which comparisons of different forms of treatment of the toxemias could be made.

About sixty pages are devoted to references, and many lists are disproportionately large. For example, seven pages of references are devoted to the fetal membranes and eight to the changes in the maternal organism but only one and a half pages of references are assigned to the management of pregnancy, only one page to the management of labor, only one page to combined placenta previa and accidental hemorrhage and only two and a half pages to the toxemias of pregnancy.

The author still speaks of "medical complications of pregnancy" when referring to the occurrence of pregnancy in women with heart disease, pulmonary tuberculosis and diabetes. In these associations it is the pregnancy which is the complication of the illness and not vice versa. There is a full page illustration of the Walcher position in spite of the fact that James Young and others have proved by radiographic means that this position does not enlarge the pelvic inlet, as was formerly believed.

In spite of these criticisms the book is an excellent textbook of obstetrics. It is well written, the type is clear and, except for the roentgenograms, the illustrations are highly instructive. The popularity of the book is deserved and the volume will undoubtedly retain its place as one of the leading textbooks on obstetrics.

Psychologic Care During Infancy and Childhood By Ruth Morris Bakwin BA MA MD Assistant Clinical Professor of Pediatrics New York University College of Medicine New York and Harry Bakwin BS MD Associate Professor of Pediatrics New York University College of Medicine Cloth Price \$3.50 Pp 317 with 31 Illustrations New York & London D Appleton Century Company Incorporated 1942

This is a book written by two pediatricians rather than by orthopsychiatrists, and consequently the point of view is modified by the failure of the authors to understand some of the more deep seated psychologic factors. In general, however, the book covers a vast amount of data, some of which would be of value to the pediatrician, some of value to the psychologist and much of a great deal of value for the physician who has the task of caring for children and their parents. There are thirty-four chapters, which means that such important topics as poor sleep is given only three pages, the adjustment of the child to nursery school is given less than one page and parental overprotection, which is the problem most frequently met in child guidance clinics, has only one page, so that the whole field of child psychology is covered widely but not deeply. The first six chapters of the book deal with basic principles, history taking and the diagnosing of psychologic problems. The next six chapters cover special psychologic considerations such as emotions and mentality, while the remainder of the book consists of scattered topics some of which deal with special problems such as lateral dominance, special types of mental deficiency, disturbances associated with physical states and other more general topics such as play training or school problems or the sick child's psychology. Some of the material, such as that of lateral dominance and lefthandedness, is not consistent with general beliefs on the subject, and much more emphasis is placed on mental deficiency than is needed in a book of this sort. The chief defect of the book is an overemphasis of a multitude of specific features and an underemphasis of dynamic considerations in causes of maladjustment of the child in the home, in the school and under the care of the physician. Nevertheless this is the kind of book for a person who needs a complete survey as an introduction to deeper, more comprehensive and perhaps more useful books on child psychiatry and developmental psychology.

Atlas of Ovarian Tumors By Gemma Barzilai MD Preface by Fred W Stewart MD Pathologist Memorial Hospital for the Treatment of Cancer and Allied Diseases New York City Cloth Price \$10 Pp 261 with 258 Illustrations on 58 plates New York Grune & Stratton 1943

This is an atlas of microscopic diagnosis. As stated in Dr Stewart's preface, it is timely and complete. The illustrations are good. The morphology, genesis and other features of each ovarian neoplasm are described systematically in the text, but the literature is not reviewed except that helpful lists of synonyms are given. Treatment is not discussed in detail. The statements about radiotherapy are only general and are sometimes vague. Writing about dysgerminoma (p 97) the author says that "the tumor is extremely radiosensitive and the destroying dose is about one third of the dose usually needed to control a cancer." We are not told, however, what the controlling dose of cancer is. The publisher's part is well done. The paper and the print are first class, the plastic binding works smoothly, but much space is wasted in wide margins and empty backs of plates. The atlas will be of valuable service to clinicians and pathologists in their work with ovarian neoplasms.

The Horses of the Sun By Dr Kathryn M Whitten Cloth Price \$2 Pp 314 Boston Meador Publishing Company 1942

This is a novel written by a physician which deals with the life of a spinsterish New England girl who first goes into nursing and then, after showing her executive ability and medical ingenuity when the survivors of a train wreck are brought into the hospital where she is working, is encouraged to go into medicine. The work not only deals with the seamy side of her life before her entry into the medical profession but also tells of her struggle against some of the less prepossessing members of the profession, particularly those whose ethics are definitely below par. Dr Whitten's style is somewhat stilted. It probably would be of more interest to the layman than to the physician, but the physician would realize that most of the unsavory characters are not typical of the medical profession.

Religion and Health By Seward Hiltner Cloth Price \$2.50 Pp 292 New York Macmillan Company 1943

It might appear on first inspection that this book had been improperly titled. Such an impression would be erroneous, because the author is referring to "total health." He has realistically recognized and stressed the fact that mental and physical health cannot be treated as separate entities. Although the major contributions of the book are related to psychologic problems, the physical, particularly the physical which is closely related to the psychologic, has not been neglected. In some respects this is a difficult book to evaluate. Parts of it are exceptionally good, while other parts are vague and sometimes misleading. For example, the author states on page 23:

"mental hygiene is not to be equated with science. It is more nearly akin to technology, but it contains certain assumptions which are more closely related to religion than they are to science." While the author attempts to show proof for this statement, the proof appears entirely unconvincing. There are other equally challenging statements relative to religion and mental hygiene which the reader must study and evaluate for himself. In spite of these criticisms the book can do no harm and may well prove of great value, especially if it reaches even a small minority of an all too extensive public that is almost completely uninformed regarding our present knowledge of psychologic and sociological problems. It is obvious that the author has considerable insight into the psychologic and sociological problems of our present society. His attempt to transmit his information and insight to the clergy and the parish is both ambitious and praiseworthy. How much success will attend his efforts only time will tell. The pages which he devotes to psychosomatic research alone are worthy of wide publicity. This comparatively new and extremely important field for investigation should be publicized by every humanitarian. The author could well have included more recent findings and reports in this and other allied fields, but interested readers will find this book and the reference material, which is carefully listed, as excellent groundwork for further study. The book is well written in language that is easily understood. Psychiatric jargon is either eliminated or carefully defined. Although the author must have read considerable psychoanalytic literature, the contributions of psychoanalysis to the understanding of human behavior have been given small credit. In fact there are references to psychoanalytic contributions as products of the mental hygiene movement. While this may be confusing to the psychiatrically oriented reader, it does not detract from the value of the book.

Diet Manual Mount Sinai Hospital Philadelphia Third edition Loose Leaf Paper Price \$2.50 Pp 71 Philadelphia 1942

This gives a complete list of therapeutic diets as used in a modern hospital. The diets are given in actual food portions as well as in caloric units, and sample menus are included. A section on the feeding of children has been added. A valuable feature of the volume is the inclusion of some general considerations on the procedures and principles of particular dietary practices. References to the medical literature indicate the original sources of information. This collection should be of interest and use to other institutions and to private practitioners in the construction of diets for use in the home. However, its present multigraphed and paper covered format makes it somewhat difficult to read and handle.

Essentials of Nutrition By Henry C Sherman and Caroline Sherman Lanford Columbia University New York Second edition Cloth Price \$3.50 Pp 442 with 34 Illustrations New York Macmillan Company 1943

Since the publication of the first edition of this book, a national nutrition program has been outlined by the National Research Council has set up its recommended daily allowances for specific nutrients. The new edition of this book reflects this progress. Moreover, there have been additions to the known vitamins, especially in the field of the so called vitamin B complex. The present edition calls attention to these additions and makes available references to the periodical literature on the subject.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT HOWEVER REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS BUT THESE WILL BE OMITTED ON REQUEST.

BILIARY COLIC OR CORONARY OCCLUSION

To the Editor—A man aged 52 Italian had an appendectomy in April 1942. Perusal of the chart shows that the appendix was gangrenous and perforated at the tip and that there was a small abscess around the tip. Drainage was maintained for about two weeks and the wound closed thereafter without further complications. A nurse once made a remark about irregular pulse in her notes but nothing further is known to either the surgeon or his associates. The man resumed his strenuous occupation as chef of a big restaurant almost immediately after his dismissal. He felt entirely well until September when he began to complain of much 'gas' and occasional pain in the epigastrium at the same time he also commenced feeling increasingly tired. On November 7 he suddenly experienced excruciating pain in the upper epigastrium. The pain was sharp and cramplike and did not radiate. The attack lasted four hours. A few hours later the patient was found to be jaundiced. I did not see him until November 10 at which time he still showed mild jaundice and bile was found in the urine. The stools were not claylike. The icteric index was 17. The urine also contained albumin 2 plus a trace of sugar and a few red blood cells and white blood cells. The white blood count was 14,000. Clinically the heart was definitely enlarged to the left. Its action was rapid and entirely irregular. No murmurs were heard. The blood pressure was 130 systolic 85 diastolic. The liver was just palpable below the costal margin. There was no tenderness no evidence of fluid anywhere in either the thoracic or the abdominal cavity and no edema. The pulse was 114 entirely irregular. Respiration was 20 a minute. A cardiogram showed auricular fibrillation. The patient was placed on a fat free diet with medication of bile salts and was digitalized at the same time. One week later the jaundice had disappeared the liver was no longer palpable and there was no dyspnea. The ventricular rate had fallen to 84. Fibrillation is of course still present. The patient is now entirely free from complaints and wishes to return to work. I should deeply appreciate an opinion as to the most probable diagnosis and prognosis further treatment and how long the patient should be kept away from work. M D Massachusetts

ANSWER—Before the prognosis and management of this case can be appraised, a more definite diagnosis is necessary. The attack of November 7 sounds much like biliary colic. The correctness of this diagnosis should be confirmed by a cholecystogram. Another possibility to be considered is that the attack of November 7 might have been coronary occlusion. Judging from the description given, the jaundice was out of proportion to the other symptoms present and hence much more suggestive of biliary colic than of coronary occlusion. However, the cardiac findings given suggest that occlusion might have occurred. Serial electrocardiograms would be helpful in this regard. If cholelithiasis is found, it may be assumed that the attack of the 7th was biliary colic. The enlargement of the heart, fibrillation and probable cardiac decompensation would then be ascribable to some other cause, perhaps arteriosclerotic heart disease. If gallstones are found, the question arises as to whether operation should be advised. The patient probably would survive such an operation. However, if this was the first attack of biliary colic, the more conservative procedure might be to defer operation until further attacks occur. If no gallstones are found coronary occlusion is the most likely diagnosis. In this circumstance it would be well to advise the patient to remain away from work for a total period of three months if possible and then return to light work. The administration of digitalis should be continued.

The trace of sugar in the urine is probably not significant and could be checked by additional urine examinations and a fasting blood sugar. The albumin may well be due to the cardiac decompensation. The few red and white blood cells are probably not significant.

IMMUNIZATION OF STUDENT NURSES TO SCARLET FEVER

To the Editor—What is the present status of the question of immunizing student nurses in a general hospital against scarlet fever?

William E Bayley M D La Crosse Wis

ANSWER—Testing for susceptibility and immunization of susceptibles against scarlet fever in the student nurses has been adopted as a routine procedure in a number of the larger general hospitals located in climates where scarlet fever is prevalent.

RESORCINOL DYES AND RESORCIN DERMATITIS

To the Editor—I am a practicing surgeon and for the past years have been having frequent attacks of what has been diagnosed by capable dermatologists as contact dermatitis due to resorcin. I have no resorcin in my office and come in contact with none at the hospital. Is it possible that resorcin is used as a dye in upholstered furniture or in clothing and could I be getting my contact dermatitis from such exposure? If so could you tell me in what type or color of clothing or upholstering resorcin may be used as a dye? M D Iowa

ANSWER—Resorcin is an ingredient in a number of dyes. The following is a list of dyes in which resorcin is one of the chemicals used in manufacture.

1 Resorcine Brown, also known as Aceko Phosphine G, Tropeoline NRN, Orange Special AP and Resorcine Brown G. The components used in the manufacture of this dye are sulfanilic acid, meta-xylydine and resorcinol. This dye is used mainly for dyeing leather but it will also dye wool.

2 Resorcine Dark Brown, also known as Fast Acid Brown, Amacid Fast Brown, Resorcine Brown RN and Aceko Dark Brown RD Fast Brown. The components used in manufacturing this dye are naphthionic acid and resorcinol. It is used for dyeing wool.

3 Resorcine Yellow, also known as Phosphine Substitute, Chrysoine, Yellow T, Pure Yellow for wool N, Gold Yellow, Tropaeoline O, Acme Yellow, Chrysoiline and Orange RL. The components of this dye are sulfanilic acid and resorcinol. It is used mainly for dyeing silk and leather.

4 Nitroso Blue MR, also known as Resorcine Blue, Nitroso Base M and Tannoxydophenol. The components of this dye are resorcinol, p-Nitrosodimethylamine, hydrochloride and tan nin. It is used in calico printing and also dyes cotton.

5 Fluorescent Blue, also known as Resorcine Blue and Iris Blue. The components are resorcinol, nitroso resorcinol and brominate. It is used for dyeing silk and to some extent for dyeing wool.

6 Resorcine Brown 5 G, an azo acid dye made by du Pont.

7 Resorcine Brown 3 R, an azo acid dye made by du Pont.

8 Resorcine Green No 1.

As can be judged from this list, resorcin may be an ingredient of dyes used in silk, wool, cotton and leather.

Resorcin is a phenol, and if one is sensitive to resorcin it is possible that one may also be sensitive to carbolic acid or materials containing it.

The resorcinol used in the manufacture of the dyes mentioned is supposedly completely combined with the other components, forming an entirely new chemical compound. It is possible, but not probable, that in some batches of these dyes the resorcinol is not completely combined or is in excess. In such cases it would be possible for one hypersensitive to resorcinol to develop a dermatitis from contact with fabrics containing such imperfect resorcinol dyes.

STEAM RADIATORS AS POSSIBLE CARRIERS OF INFECTIONS

To the Editor—I have often wondered if steam radiators might be possible carriers of infectious diseases including the common cold in apartments, offices and schools and if so has any thought been given to this problem? When the heat is on, the radiators and their connecting pipes contain steam and the condensation moisture which returns to the heating unit. When the heat is discontinued or diminished as happens at night, air from the room is drawn in through the radiator valve to occupy the space the steam has vacated. When the steam pressure is increased, air is expelled through the radiator valve. Naturally allowance must be made for the size of the heating unit space heated distance from the heating unit and if height is sufficient to require a steam pump. Does the expelled air represent the same air which was drawn from the room or is it a mixture of air from other heated spaces? This withdrawn air and the expelled air are not heated other than possibly that portion in direct contact with the steam. Would this be a possible carrier? Some radiators have traps on them but many do not.

George P Nicholson M D Chicago

ANSWER—There is no information available as to whether steam radiators might become carriers of infectious diseases under the conditions described. Such a possibility would be limited largely to one-pipe steam heating systems installed in inexpensive homes and apartment houses. The system is generally undesirable for other reasons, particularly noise ('water hammer') and offensive odors in the air discharged into the room from the air valves. Whether organisms can live long in the pungent and humid atmosphere inside the radiators is another question.

Large buildings are heated by vapor or vacuum systems which have no radiator air valves. The air is vented in the basement or discharged outdoors.

LIGHT WORK FOR PATIENT WITH OCCASIONAL TUBERCLE BACILLI IN SPUTUM

To the Editor—Would it be advisable for a young physician to engage in part time (institutional) work while having an occasional sputum specimen positive for tubercle bacilli? The patient has been in a tuberculosis hospital continuously for the past thirty months. On admission the diagnosis was bilateral infiltrative lesions with endobronchial tuberculosis. No evidence of cavitation was ever found on repeated examinations (including laminography). Endobronchial lesions have been found to be (1) a granuloma which cleared up (2) ulceration also now cleared and (3) tubercle also cleared up. In spite of negative bronchoscopic findings there has been an occasional positive sputum specimen (every third month). Parenchymal lesions have been checked. As these findings of positive sputum have been present for the past fifteen months without any apparent reasons for them the patient would like to know if he couldn't work three to four hours a day so as to keep his mind occupied as now he is repeatedly becoming depressed and discouraged (also because of his lack of interest in things in general as the only diversions opened to him at the institution are reading and the radio).

M D New Jersey

ANSWER—When it is advisable for a tuberculous patient to resume work is dependent on several factors. A considerable number of patients who have their disease brought under control so as to have no clinical manifestations and whose lesions appear to be well stabilized continue to have tubercle bacilli recovered occasionally from the sputum. Others who apparently have no sputum have bacilli revealed in gastric washings. Indeed this is true of a good many persons who have been adequately treated and discharged from hospitals and sanatoriums. It is not surprising when one considers that no present method of treatment destroys tubercle bacilli and that they may remain alive in large numbers in old apparently well controlled lesions the entire lifetime of the individual. More accurate methods of examining for tubercle bacilli and more frequent examinations are bringing to light the fact that tubercle bacilli are occasionally eliminated in many so called arrested cases of tuberculosis. This may occur with no evidence of reactivation of old lesions or appearance of new ones. Unfortunately, one is never certain as to the exact source of the tubercle bacilli and therefore one is likely to be suspicious of nondemonstrable spread of an area of disease or the development of a new lesion still so small or so located that it cannot be demonstrated by present methods of examination.

It appears that an excellent therapeutic result is being obtained in the case of this young physician. This is particularly true of the endobronchial lesions. However, there remains the possibility that other lesions beyond the areas visualized by the bronchoscopist may not be as well controlled as those seen and therefore may be responsible for the tubercle bacilli occasionally found in the sputum. Moreover, there may still be small areas in the region of the parenchymal disease which are still eliminating tubercle bacilli. After thirty months of excellent institutional care with such an apparently good clinical result and with no evidence to the contrary it would seem safe to institute graduated exercise in the form of light work about the institution under most careful observation, using the necessary precautions to protect fellow workers and patients against possible infection.

PRIMARY TUBERCULOSIS COMPLEX

To the Editor—A patient has just been rejected in the army draft for tuberculosis pulmonary primary complex unstable. The meaning of primary complex unstable is unknown to me. Does this mean an active or an inactive tuberculous lesion? I presume the lesion is in the parenchyma.

Nina C Wilkerson M D Sturgis Mich

ANSWER—In the majority of persons with primary tuberculous complexes the only evidence of its existence during life is the reaction to tuberculin. There are no symptoms, physical signs or x-ray shadows to aid the physician in determining the location of the lesions. This may be because (1) the lesions do not attain sufficient size to cast shadows visible on the x-ray film, (2) the lesions may be located in that 25 per cent of the lung which is not visualized on the film and (3) the primary lesions may be located in parts of the body other than the lungs. However, in such persons lesions can be found when sufficiently careful postmortem examinations are made.

In a smaller number (usually not exceeding 30 per cent) of persons with primary tuberculosis complexes, evidence may be found of calcium deposits in the pulmonary parenchyma the hilus region or both by fluoroscopic or x-ray film inspection. Obviously not all of such deposits represent tuberculous lesions, since there are other causes of calcifications in the lungs.

In an extremely small number (3 to 5 per cent) of persons with primary tuberculosis complexes evidence of the lesions appears in the parenchyma of the lung about the time the tissues become allergic. There may or may not be temperature elevation but, if so it usually does not persist for more than one to three weeks. If other symptoms are present they are not unlike those of a common cold or influenza. Usually there are no abnormal physical signs. The red blood sedimentation rate may be increased for a few weeks. When the lesion is located in that part of the lung which is visualized by the x-ray film it casts a dense, homogeneous shadow which varies in size from one barely large enough to be seen to one involving an entire lobe. This is due either to (1) collateral inflammation around the primary lesion in the lung or (2) atelectasis as the result of occlusion of a bronchial ramification caused by enlarged regional lymph nodes. If the former the shadow may remain unchanged for many months after which it slowly disappears. By the time the original shadow is no longer visible or at some later time there may appear one or more small, sharply outlined dense shadows which represent calcium deposits that began as microscopic areas and gradually attained macroscopic proportions. Throughout this period there usually is enlargement of the hilus shadows on the same side probably because of the tuberculous lymph nodes which have become a part of the primary tuberculosis complex. As the primary lesion in the parenchyma subsides, the regional lymph nodes become smaller and calcium deposits may be visualized in them about the same time as they are seen in the lung parenchyma. Apparently the patient's condition belongs to this small group in which the primary parenchymal lesion is found while the collateral inflammation is present or the regional lymph nodes are large enough to obstruct a bronchial ramification.

To determine that the lesion is tuberculous required the presence of a characteristic tuberculin reaction. Tubercle bacilli may also have been found in the sputum or gastric washings, or several x-ray film inspections were made of the chest to demonstrate the chronicity of the lesion.

When the disease was found to be tuberculous there must have been a record of repeated tuberculin tests previous to the complete examination to justify a diagnosis of primary disease. In other words this patient must have been known to be a nonreactor to tuberculin and to have become a reactor about the time the examination was made. By single x-ray film inspection it is impossible to differentiate between primary and reinfection types of lesions. Moreover it is not possible to differentiate between tuberculous and nontuberculous lesions since there is no absolutely characteristic shadow of any disease. If tubercle bacilli were found in the gastric contents they may have emanated either from a primary or a reinfection type of lesion since in this manner bacilli may be recovered in about 25 per cent of persons with primary lesions in the pneumonic stage.

To determine that the lesion is unstable required a period of observation. Primary tuberculous lesions change so slowly that a single examination including all its phases does not suffice to determine their stability.

The words active and inactive with reference to tuberculous lesions should be used exclusively in connection with the reinfection type of tuberculosis. Primary pulmonary lesions differ so much in their behavior from the reinfection type of lesions that they could easily be regarded as an entirely different disease entity. Indeed primary lesions begin to develop on tissues that are not sensitized to tuberculin and therefore the reactions to them are nonspecific, in fact no different during the first few weeks than the reactions of the tissues to such inanimate objects as particles of silica. Therefore, in the early stages of their development primary lesions are extremely benign. Even when a lesion is decreasing in extent it may be considered pathologically active. However, the usual conception of the word activity is that it indicates progressive clinical disease. Progressive primary pulmonary lesions apparently are extremely rare. Most of them gradually recede and never present clinical manifestations.

SASSAFRAS TEA SUBSTITUTED FOR COFFEE

To the Editor—Is there any evidence to support the belief that substitution of sassafras tea as a beverage for coffee would prove harmful?

Joseph H Kinnaman M D Ponca City Okla

ANSWER—There has not been any evidence found to support the belief that sassafras tea would be harmful when substituted as a beverage for coffee.

CONDITIONS CAUSING CONFUSION IN THE DIAGNOSIS OF RHEUMATIC FEVER IN CHILDREN

ANALYSIS OF DIAGNOSES MADE BY PRACTICING
PHYSICIANS IN 271 RHEUMATIC SUBJECTS

ARILD E. HANSEN, M.D.
MINNEAPOLIS

The protean symptomatology of rheumatic fever undoubtedly, in many instances, accounts for the difficulty encountered by physicians and medical students in the correct diagnosis of this disease. The fact that textbooks mention as many as fifty different clinical conditions whose manifestations are such that they might, under certain circumstances, be considered in making a differential diagnosis of rheumatic fever¹ tends to make more complex rather than to simplify the arrival by physicians at the correct diagnosis. Because early recognition and treatment comprise at the present time our most effective weapon in combating this devastating disease of childhood, confusion and delay in correct diagnosis may have far reaching and serious results.

The belief that a practical approach to this problem might lie in a study of the disorders which are most frequently confused with rheumatic fever by the practicing physician prompted me to review the diagnoses made by physicians referring to the University of Minnesota Hospitals all children who later proved to have rheumatic fever. This procedure was facilitated by the fact that all patients admitted to this hospital must present a letter or note from their physicians wherein diagnosis and reason for referral are given. The majority of these physicians are general practitioners, although a considerable number of children are referred by pediatricians. This report presents and summarizes the diagnostic possibilities given by the referring physician and those made by the admitting intern and resident staff for the 271 children with rheumatic fever under 16 years of age observed in the outpatient cardiac disease clinic and the inpatient service of the Department of Pediatrics of the University of Minnesota Hospitals during the years 1928 through 1941.

Of the 271 children with rheumatic fever who were referred to the hospital and outpatient clinic, the admitting and final diagnoses agreed essentially in 181 instances. As regards the other 90 cases, the admitting diagnosis was inadequate or disagreed entirely with that

finally made. I realize, of course, that in many instances it was only because of the advantages of the longer periods of observation and our better laboratory facilities that the diagnoses were able to be made with considerable certainty. In 20 of these, however, the referring statement mentioned several of the predominant symptoms, in most of these cases, the diagnosis of rheumatic fever could well have been made. Failure to do so was probably due to the fact that the physician did not wish to commit himself to a specific diagnosis. It probably is worth while to emphasize that, when such symptoms as "growing pains, leakage of heart," "heart murmur, growing pains, low grade fever," "fever, fast pulse pain and weakness in legs," "arthritis of hands, elbows and knees," "stiffness of legs and hips," "swollen and stiff joints," "joint pains," "heart case following pneumonia," "anemia, poor heart, infection," "pains and stiffness in hands gas pains" and "nervousness, purposeless movement" are given, the diagnosis of rheumatic fever should be readily suspected and more exact diagnostic statements made.

To facilitate presentation of the information obtained regarding the conditions which most frequently were found to have caused confusion in the diagnosis of rheumatic fever, the data are presented in tables 1 to 6 according to several of the major groups of manifestations of the disease. The findings here reported in these tables do not refer to the relative frequency with which the various manifestations of rheumatic fever were found to occur under these conditions but simply to the types of manifestations which appeared to cause confusion in making the original diagnosis on the part of the physicians at the time these patients were referred to the hospital.

The most common symptom which appeared to cause difficulty in the diagnosis of rheumatic fever in this series of cases was pain in the abdomen. In 19 instances the inability to make the diagnoses undoubtedly resulted because of the prominence of this symptom. The diagnoses given in these cases are summarized in table 1.

It is well known that abdominal discomfort or real pain frequently occurs in patients who have active rheumatic infections, however, it is rather surprising that the pain could be so confined to this region as to cause appendicitis to be suspected in so many instances (table 1). This fact serves to emphasize that, in any differential diagnosis involving abdominal pain in children of school age, rheumatic fever must be considered as a possible cause. On several occasions in these subjects my associates and I have felt somewhat embarrassed to advise removal of an appendix only to have polyarthritis or choreic symptoms become prominent shortly after. The diagrammatic representation of the course of events in a 14 year old boy who illustrates such a type of case is presented in the accompanying chart. This child had had abdominal pain and vomiting for two days before admission to the hospital and on

Assistance in the preparation of these materials was furnished by the personnel of the Works Projects Administration Official Project No. 165-171-440 Subproject No. 254.

1. Hansen, Arild E. The Differential Diagnosis of Rheumatic Fever in Children. *Nebraska Medical Journal* 26:159-163 (May) 1941.

examination was found to have tenderness in the right lower quadrant of the abdomen. Appendectomy was performed shortly after his arrival but no inflammation of the appendix, mesenteric lymph nodes or intestine was found and no Meckel's diverticulum was present. Polyarthritides developed the day following operation and he continued to have evidences of activity of the infection for the next three months. On the other hand, in 1 instance acute suppurative appendicitis actually was present in a child with an active rheumatic infection. Therefore, if any doubt exists as to the possibility of an acutely inflamed appendix, operative intervention is fully justified to avoid the consequences of rupture with peritonitis.

As regards the subjects who had symptoms referable to the joints and extremities in whom the diagnosis of rheumatic fever was not made, the conditions mentioned

due to the desire on the part of the physician or parents for the patient to obtain early treatment by the Sister Kenny method, which is being carried on in these institutions. Conversely, we have seen a number of other patients suffering from infantile paralysis who were actually diagnosed as having acute rheumatic fever and treated for it. In certain instances the differential diagnosis between these two conditions may be difficult early in the course of the disease, which situation is especially true in the presence of an epidemic of poliomyelitis. One may well say from a practical point of view, therefore, that another of the important conditions which may cause confusion in the differential diagnosis of rheumatic fever is poliomyelitis.

It is not surprising that acute osteomyelitis may be considered a likely diagnosis in certain cases of acute rheumatic fever as occurred in 3 instances in this study

(table 2). As in poliomyelitis the opposite situation also arises quite frequently, namely that the patient with acute osteomyelitis is thought to have acute rheumatic fever. This seems to be one of the more difficult differential diagnoses to make even for experienced resident physicians. But 1 patient was thought to be suffering from a tuberculous joint. As regards the other conditions included under miscellaneous diagnoses in those patients having pain in the extremities as a prominent feature there seems to be little reason why the diagnosis of rheumatic fever should not have been made when "heart murmurs, growing pains, low

Diagrammatic representation of the course of events presented by a 14 year old boy who was referred to the University of Minnesota Hospitals with the diagnosis of acute appendicitis. For the two days preceding admission he suffered from abdominal pain and vomiting and on examination was found to have tenderness and rigidity in the right lower quadrant of the abdomen. Exploratory operation revealed no inflammation present in the region of the appendix, mesenteric lymph nodes or intestine. No Meckel's diverticulum was present. The day following operation pain swelling and tenderness developed in the right knee and the next day the right wrist and left hip were similarly involved. Electrocardiographic signs of myocarditis developed and evidences of the activity of the rheumatic infection persisted for three months. This case is quite typical of those subjects with rheumatic fever who have abdominal pain as a prominent symptom of rheumatic fever.

in the referring statements for the 13 patients in this group are listed in table 2.

Although only four referring physicians gave poliomyelitis as the diagnosis (table 2), on careful study of the histories of a number of other patients it was found that infantile paralysis was suspected early in the course of the disease. In 1 other instance the working diagnosis probably was poliomyelitis in view of the statement submitted on admission as regards the reason for referral, namely "fever, fast pulse, pain and weakness in legs." Recently at both the University of Minnesota Hospitals and the Minneapolis General Hospital, several patients not included in this study have been sent in with the diagnosis of poliomyelitis. The fact that more of these cases whose symptoms are such as to suggest poliomyelitis are now being seen is probably

grade fever," "swollen and stiff joints" and "leakage of heart, growing pains" were the symptoms present. On the whole, when the symptom of pain in the region of the joint was present in the cases studied, the diagnosis of rheumatic fever was readily made.

The skin manifestations of 3 patients were sufficiently prominent to cause difficulty in diagnosis (table 3). Rocky Mountain spotted fever, allergic dermatitis and symptomatic purpura were the diagnoses given.

The diagnosis of acute nephritis was given in 3 cases (table 3). It is well known that evidences of nephritis occur fairly frequently in patients with rheumatic fever. Only 1 child was thought to have pyelitis, and this seemed to be an exclusion diagnosis in that the patient had prolonged fever, and a few clumped leukocytes were found in the urinary sediment.

When carditis occurred as the first manifestation of rheumatic fever, the diagnosis was quite frequently missed. In examining the records of a number of such cases, the diagnosis of "flu" was frequently made early in the course of the disease. Such diagnoses as septicemia, acute septic endocarditis, as mentioned in the referring diagnoses (table 4) indicate that patients with acute rheumatic fever may present a clinical picture which simulates that of sepsis. None of the 6 patients who were believed to have subacute bacterial endocarditis actually were suffering from this condition.

In 3 instances the diagnosis of pneumonia was made, and, in a fourth, heart disease was believed to have complicated a previous attack of pneumonia (table 4). In 1, acute bronchitis was given as the diagnosis, in another, pleurisy with effusion. Even though the manifestation of undulant fever may simulate rheumatic fever, this condition was mentioned only once in the referring diagnoses.

Regarding the miscellaneous diagnoses made by the referring physicians in such cases when "low grade fever," "anemia, poor heart" were given as the diagnoses, the diagnosis of rheumatic fever may well have been made. In spite of the frequency with which the tonsils are blamed for causing various symptoms, it is rather remarkable that "infected tonsils" was given

as the diagnosis on only 2 occasions (table 5). Although epistaxis occurs frequently in rheumatic fever, in only 1 case was this the most prominent symptom. Emotional upsets may occur in rheumatic fever patients even though chorea minor is not present. In 1 "irritable, restless" and another "old sinusitis" were mentioned in the letter, and a third was believed to be a psychiatric case. One child was believed to have a possible deficiency disease. Of all the rheumatic subjects referred to the hospital, in only 3 was the diagnosis considered to be congenital heart disease.

The data regarding the diagnosis of chorea are presented in somewhat more detail to show that this condition is correctly diagnosed in a high proportion of cases (table 6). In 96 of 271 subjects studied, chorea was manifest on admission to the hospital and there was agreement in the diagnosis in 73 instances. On 3 occasions the diagnosis was given as rheumatic fever alone and in 1 no diagnosis was given. On the other hand, in 5 instances the admitting diagnosis of chorea was made, but this was not confirmed by the hospital staff. In these cases the choreic symptoms may have subsided by the time the patient came to the hospital. Of the other 19 cases of chorea, "nervousness" was mentioned as the prominent symptom in 4 instances and in 1 of these "nervousness and purposeless movements" was the statement given. The presence of emotional dis-

turbance seemed to be the major evidence in but 1 case, whereas in 1 other "difficulty in hearing and speech" was the most noticeable feature. One type of case was encountered which was equally perplexing to both the practicing physician and the hospital staff, namely that

to suspect the possibility of some other disorder. Three such cases have been observed in our clinic during the past twelve years and in none of these was there evidence of acute encephalitis, birth trauma or other neurologic conditions which, if noted, would tend to refute the diagnosis of chorea minor. Probably the most surprising fact is that in 4 children with chorea, appen-

ditis was the admitting diagnosis. I have referred already to the prominence of the symptom of abdominal pain in rheumatic fever.

Although this study shows that the diagnosis of chorea minor was accurately made by the practicing physician in a high proportion of cases, more detailed

review of the case histories revealed that in many instances the diagnosis could well have been made earlier in the course of the disease. To facilitate early diagnosis especially in the mild cases, the physician should be thoroughly familiar with the main clinical features of this encephalitis of rheumatic origin. The presence of dystonia, muscle weakness, personality change and emotional disturbances in children of school age leads one to suspect chorea. In addition to help in early diagnosis, part of the physician's routine examination should consist in subjecting patients to one of the finer tests for choreic activity. A number of procedures are used to detect evidences of disturbance in finer movements, the one used in this clinic was popularized by Dr. Irvine McQuarrie. The patient while sitting comfortably is asked to place his hands palm downward lightly on the hands of the examiner which are held palm upward, and to place his tongue gently between the lips without biting and to remain very quiet for a few moments. Evidences of uncontrolled movements may be readily detected in this way. Even the 5 or 6 year old is able to be very still for several moments under these conditions. Muscle weakness and instability can be detected by asking the child to squeeze steadily the fingers of the examiner. Pointed questions directed to the mother regarding the emotional status of the subject often will give one informative clues in making the diagnosis of chorea. Such a routine is especially valuable for patients who have had previous attacks of rheumatic fever or for those with a history of rheumatic fever in the family.

COMMENT

The fact that rheumatic infections may involve so many tissues and vary to such a great extent in intensity makes it rather surprising that a wider variety of conditions was not mentioned by the practicing physicians when these rheumatic subjects were referred to the hospital. Of interest is the fact that at no time did such conditions as pyogenic arthritis, syphilis, scurvy, serum sickness or trichinosis, which are commonly mentioned as likely to be confused with rheumatic fever,

cause difficulty in diagnosis in these cases. Judging from the nature of the symptoms mentioned, with a little more care at least 15 of the 90 cases not diagnosed as rheumatic fever could well have been so diagnosed. We may say then that real difficulty was encountered in about 75 cases. The findings as regards the conditions which caused distinct confusion in diagnosis are summarized in table 7. Probably most significant from a practical point of view is the fact that in 19, or one fourth of the total in which the wrong diagnosis was made, the presence of abdominal pain was the outstanding symptom which interfered with making the correct diagnosis. In the past two months 3 additional patients have been referred to the University Hospital with the diagnosis of acute appendicitis, each of whom on further study was found to have acute rheumatic fever. The causes of pain in the abdomen are numerous, but this study should emphasize the importance of rheumatic infection as being one which must be considered in the differential diagnosis of appendicitis.

In patients having pain in the extremities as an outstanding symptom, acute polyomyelitis and acute osteomyelitis are disorders which may be difficult to differentiate from rheumatic fever. The objective evidence of erythematous and purpuric lesions as well as findings of nephritis occur frequently enough in rheumatic fever to call to mind the possibility of rheumatic fever when those conditions are present. The fact that rheumatic fever may manifest itself as a severe or even an acute fulminating infection should be borne in mind by those who are called on to see children. It may be pointed out again that subacute bacterial endocarditis occurs far less frequently in children than in older subjects. As regards the miscellaneous conditions listed, probably more would have been diagnosed as rheumatic fever if the physician had been fully aware of the nature of the nonspecific constitutional or general symptoms that occur in children with mild rheumatic infections. A high percentage of cases of chorea minor are diagnosed correctly by the practicing physician, and the failure to do so seemed to occur when the symptoms were mild. Unquestionably chorea minor could be diagnosed earlier and more frequently if the physician routinely subjected the child of school age to one of the finer tests for muscle tonus.

TABLE 7—Summary of Conditions Which on Admission to the Hospital and Outpatient Clinic Appeared to Cause Real Confusion in the Diagnosis of Rheumatic Fever from a Study of the Diagnoses Made by Physicians in Referring 271 Children Who Proved to Have Rheumatic Fever

C Skin manifestations	2
D Kidney and bladder (nephritis 2)	4
E Acute febrile illness—severe infections	14
F Mild rheumatic infections	11
G Various symptoms of chorea minor	18

Another approach to the problem of the differential diagnosis might be made by studying the records of patients with various conditions to determine whether or not rheumatic fever had been considered in the differential diagnosis during the course of the disease. There are certain disorders which may have a number of features which are very similar to those found in patients having rheumatic infections. For example, our experience in confusing leukemia with rheumatic fever has been duplicated a number of times. About

four years ago a previously well 5 year old boy was admitted to the University Hospital because of an acute febrile illness of about one week's duration. He continued to have fever up to 103 and 104 F and complained of pain in the legs. He had slight epistaxis, and a faint systolic murmur was elicited. For a period of three weeks the diagnosis of acute rheumatic fever seemed to be entirely in keeping with the clinical and laboratory findings. Finally the spleen became enlarged and evidences of immaturity of the lymphocytes developed. Leukemia had been suspected but no conclusive indications developed until almost four weeks after the onset. Detailed case reports presenting similar phenomena have been reported by various workers.² Meningococcemia also may produce a clinical picture which simulates rheumatic infection. Dyson³ recently reported that a boy aged 10 years suffered for nearly four weeks with polyarthritis, which appeared to be typical of the type seen in rheumatic fever. Blood cultures revealed meningococci just about the time slight rigidity of the neck developed, that is, one month after the onset. The response to sulfonamides was prompt. The fear of using sulfonamide compounds in acute rheumatic fever because of the possibility of accentuating the symptoms prevented the earlier use of the drug. Undoubtedly a number of other conditions may produce symptoms which suggest rheumatic fever in that this disease has such a wide variety of manifestations. In fact, in view of the great variety of symptoms which may be present in rheumatic fever it could almost be said for rheumatic fever, as has been said in the past for syphilis, "to know medicine, know syphilis."

SUMMARY AND CONCLUSION

In the attempt to determine which disorders in children tend to be confused diagnostically with rheumatic fever, a study was made of the diagnoses given by practicing physicians and resident staff members with regard to 271 children with rheumatic fever who were admitted to the inpatient and outpatient cardiac disease clinic of the Department of Pediatrics of the University of Minnesota from 1928 to 1941. There was essential agreement in diagnosis in two thirds of the cases. Review of the records of the remaining cases revealed that the conditions which caused most difficulty in the diagnosis of rheumatic fever under these conditions were

- 1 Abdominal pain with possible appendicitis (about one fourth of the cases studied)
- 2 Acute anterior poliomyelitis
- 3 Acute osteomyelitis
- 4 Erythematous or purpuric skin eruptions
- 5 Evidences of acute nephritis
- 6 Acute fulminating illnesses (sepsis, pneumonia, subacute bacterial endocarditis)
- 7 Low grade infections
- 8 Nervousness in mild chorea minor

In order that the advantages gained by the early diagnosis and treatment of rheumatic infections in children may be realized to the fullest extent, the physician who is called on to care for children should be thoroughly familiar with the various and diverse manifestations of rheumatic fever.

AN EPIDEMIC OF RHEUMATIC FEVER IN A CHILDREN'S INSTITUTION

FOLLOWING AN OUTBREAK OF ACUTE TONSILLITIS

SOL P. DITKOWSKY, M.D.

NORMAL, ILL.

EDWARD STEVENSON, M.D.

BLOOMINGTON, ILL.

AND

JOSEPH M. CAMPBELL, M.D.

CHICAGO

During the later part of 1940 and early part of 1941 an unusually large number of cases of acute tonsillitis occurred in McLean County in the vicinity of Normal, where the Illinois Soldiers' and Sailors' Children's School is located. It was noted that an abnormally high incidence of acute rheumatic fever developed coincidentally or after a latent period of several weeks. The incidence of the two diseases assumed epidemic proportions in the school, where 88 children (15 per cent of the total population of 561) contracted acute rheumatic

Fig. 1—Comparison of hospital admissions for tonsillitis and rheumatic fever (fixed population 561 children) with correlation of meteorologic data.

fever. This epidemic presented an opportunity to study the relation of tonsillitis to rheumatic fever, the influence of familial predisposition, age, sex and meteorologic conditions and the significance of the patient's previous history.

At the time of the epidemic there were 561 children, 210 girls and 351 boys, living at the school. They were housed according to age and sex in twenty-six cottages. The 561 children came from 202 families. The siblings, because of differences in sex and age, lived, in most instances, in different cottages.

For the purpose of study the patients admitted to the hospital with a diagnosis of rheumatic fever were divided into three groups: (1) those with severe polyarthritis associated with fever and rapid sedimentation rates, accompanied in some instances by rheumatic erythema, nodules and carditis; (2) those with moderate or subacute polyarthritis associated in some instances with rheumatic erythema, nodules and carditis; and (3) a group of younger children with cardiac manifestations.

From the Illinois Soldiers and Sailors Children's School Hospital, Normal, Ill.

In addition to the resident staff, the patients were studied by a consulting staff consisting of an internist, two pediatricians, a roentgenologist and two bacteriologists. The bacteriologic studies of routine throat cultures revealed in some instances *Streptococcus epidemicus*. The serologic studies were performed by Drs. I.adore Lilot and D. J. Davis of the University of Illinois College of Medicine.

associated with continued fever, elevated sedimentation rates, rapid pulse, epistaxis, leg aches, abdominal pain and pallor

RELATIONSHIP OF THE OCCURRENCE OF RHEUMATIC FEVER AND HEMOLYTIC STREPTOCOCCUS INFECTIONS OF THE THROAT

Two hundred and forty-one children (42 per cent) contracted hemolytic streptococcus infection of the throat. Eighty-eight children (15 per cent of the total population) contracted acute rheumatic fever (table 1). In 51 of the 88 (57 per cent) the rheumatic manifestations developed following a follicular tonsillitis, 23

A review of the medical histories in these cases revealed that 12 children in the present series had a history of acute rheumatic fever in 1937 while living at Normal. Thirty-one of the 88 rheumatic children (35 per cent) had had a combination of the three symptoms suggestive of a rheumatic infection—attacks of fever with severe growing pains, epistaxis and abdominal discomfort. Fifty-three (60 per cent) of the children had had growing pains. In 61 cases (70 per cent) heart murmurs had been recognized prior to the epidemic of rheumatic fever, in 16 of these there was no past history of rheumatic manifestations other than the heart murmur (table 2).

The average age at onset of the primary attack was 7.6 years in those patients from whom a history of previous attack could be elicited (table 2). An average age at onset between 5 and 6 years has been reported by other observers.

Sex and Age.—Sex did not play an important role as a predisposing cause. Boys were affected as compared to girls in the ratio of 1.8 to 1, a difference not considered significant, since the normal ratio of boys to girls in the institution was 1.69 to 1. The most susceptible age group appeared to be that in which ages ranged from 9 to 14 years.

Familial Incidence.—Table 3 shows that in 63 families, a total of 173 children represented in the epidemic, 88 children (50 per cent) had manifestations of acute rheumatic fever, 30 (17 per cent) had evidence of inactive heart disease, 44 had murmurs of questionable significance and 11 had no evidence of organic heart disease. Twenty families had 2 or more children evidencing acute rheumatic manifestations.

Meteorologic Factors.—Figure 1 attempts to correlate the meteorologic data with the incidence of rheumatic fever. We notice that the peak occurred during February, although the incidence in December and January was almost as high.

The highest incidence of rheumatic infection occurred when the outdoor temperature was lowest. The percentage of sunshine and the number of clear days per month were less and the incidence of rheumatic infection was higher during the three months from December to March than during the other months. Barometric pressure changes were also more pronounced during the peak of these infections.

The incidence of symptoms and of physical and roentgen abnormalities are shown in table 4. Rashes and joint manifestations were more prevalent in children above 10 years of age, while the younger children were more prone to exhibit only the signs of carditis or chorea. Only 3 children did not show evidence of carditis. The high percentage of children having the murmurs of mitral stenosis is probably accounted for by the fact that many of the children had their primary attacks previously. Forty-eight children (51 per cent) showed an abnormality of the contour of the heart on roentgen examination, while 11 children (12 per cent) showed pronounced deviation of the esophagus, indicating left auricular enlargement.

Comment.—The epidemiology of streptococcal infections and rheumatic fever are closely related. In England, Schlesinger¹ in 1930 described the occurrence of cases of acute rheumatic fever developing in a convalescent cardiac home following an epidemic of tonsil-

of these following a latent period of ten to twenty-three days. In 21 (23 per cent) of the 88 cases of rheumatism the onset followed an infection of the upper respiratory tract, not tonsillitis. In 16 of the 88 rheumatic children (18 per cent) no history of a preceding infection of the upper respiratory tract could be obtained. The onset of the epidemic of rheumatic fever occurred six weeks after the onset of the attacks of tonsillitis, and the peak of the incidence of rheumatic fever admittances lagged eight weeks behind the peak incidence of throat infections (fig. 1).

Past History.—Most of the children at Normal come from families in the lower economic levels. They are the children of former soldiers and sailors. In many instances they come from "broken homes." A history of malnutrition, poor living conditions and inadequate medical care is usual.

¹ Schlesinger, B. The Relationship of Throat Infection to Acute Rheumatism in Childhood. Arch. Dis. Childhood 5: 411 (Dec.) 1930.

Itis Sheldon² observed a similar occurrence. Bradley³ and Glover and Griffith⁴ reported the occurrence of cases of rheumatic fever in schools in which epidemics of tonsillitis had occurred. Madsen⁵ in Denmark reported a summer epidemic of rheumatic fever following a series of milk borne hemolytic streptococcus infections of the throat. In this country, similar studies have been made by Coburn and Pauli,⁶ Zuger⁷ and Hiller and Graef.⁸ Atwater⁹ and Rosenau¹⁰ have called attention to the fact that rheumatic fever was more likely to occur during a year when streptococcal infections were prevalent. Schlesinger was among the first to call attention to the latent period between an acute streptococcal infection and the occurrence of a rheumatic infection.

The incidence of rheumatic infections following hemolytic streptococcus infection in institutions depends on the type of persons composing the population. In some institutions 6 to 14 per cent of those who had Streptococcus hemolyticus infection developed signs of rheumatic fever.¹¹ In institutions housing a rheumatic population the incidence of rheumatic fever following Streptococcus hemolyticus infection was much higher.¹² Of 241 children in our institution who had acute tonsillitis, 51 (21 per cent) contracted acute rheumatic fever. In such an epidemic, rheumatic fever may occur following a throat infection which was not recognized. Coburn believes that the attack of a hemolytic streptococcus infection is an expression of faulty immunity to the streptococcus on the part of the rheumatic patient.

Various observers state that a positive past history of rheumatic fever may be obtained in 50 to 75 per cent of patients with rheumatic heart disease. Sixty-five per cent of the children in our series gave a definite to suggestive history of a previous attack. Growing pains had been present in 60 per cent of the children. The past history of many of these children suggests that the presence of murmurs in children should not be dismissed as of little significance but should be observed. Some of the children in whom murmurs were thought to be functional later showed signs of definite valvular disease.

J. F., a white boy born Sept. 9, 1927, was admitted to the institution April 5, 1934, at which time no abnormality was noted on physical examination. One brother aged 10 has a mitral insufficiency with a history of a recent rheumatic episode. Another brother aged 18 has a loud systolic murmur at the apex transmitted to the axilla and not accompanied by a cardiac enlargement. The patient had a myositis in 1937, possibly of

rheumatic origin. He was admitted to the hospital Sept. 19, 1940 because of acute tonsillitis. Several days later an otitis media developed and a transient systolic murmur was noted for the first time. At first the murmur was variable, would disappear with a change in position and was heard best at the base. Because of a persistent elevated sedimentation rate associated with a low grade fever, the condition was treated as endocarditis. The murmur became more pronounced and was transmitted. A soft diastolic murmur could be elicited for the first time on December 13. Since then the boy has had several minor recurrent rheumatic episodes. An electrocardiogram at present

rheumatic fever patients are more than twice as apt to have another member of the family with rheumatic manifestations as not

The question arises whether the high familial incidence of rheumatic fever is based on environmental factors or whether there is a specific tissue susceptibility

Fig. 2 (case 1)—Mitral configuration on Oct. 22, 1941

Although environment no doubt plays an important factor, there is evidence to believe that tissue susceptibility is a determining factor. In our study, the rheumatic families had a greater incidence of recurrent cases than the nonrheumatic families. The K family described here is representative of 20 families in our group in which 2 or more children had manifestations of acute rheumatic fever. It is stressed that the majority of the siblings lived in different cottages, which would seem to accentuate the importance of tissue susceptibility.

THE K FAMILY

CASE 1—L. K., a well developed and well nourished white girl born March 20, 1926 and admitted into the institution on June 9, 1937, had rheumatic fever in 1936 and was hospitalized for several weeks. The admission examination did not reveal any abnormalities, but during January 1940 a systolic murmur was heard over the sternum only in the supine position.

The patient did not have any illness until Aug. 16, 1940, when she was admitted to the hospital because of pain and edema in both ankles. The heart was enlarged to the left and extrasystoles were present. A systolic murmur was not elicited until the following day. Polyarthritides and signs of decompensation developed. For ten days the temperature was septic in nature, it gradually settled to a low grade febrile response associated with an elevated pulse rate and increased sedimentation rate. Roentgen examination of the heart at that time was negative. On December 27, a diastolic murmur could also be elicited at the apex, associated with a mitral contour on roentgen examination (fig. 2).

Fig. 3 (case 2)—Heart enlarged on March 28, 1941. An esophagram showed a definite deviation of the esophagus.

CASE 2—J. K., a red haired boy born on Feb. 12, 1929, was admitted to the institution on June 9, 1937. Abnormalities of the heart were not noted on his admission examination. A systolic murmur was noted for the first time on March 11, 1940.

On December 13, 1940 the boy was admitted to the hospital because of a purulent otitis media. Physical examination

revealed that the patient was pale and had a systolic and diastolic murmur at the base and apex. A history was then obtained of a rheumatic infection during 1938 and also of recent complaints of fatigue and epistaxis. The boy had a persistent temperature of 100 to 102 F associated with a pulse rate of 110. A pronounced secondary anemia developed. Repeated blood cultures were negative. A roentgenogram taken on March 28, 1941 showed enlargement of the heart (fig. 3). On April 24, 1940 the patient had had an infection of the upper respiratory tract, and thus apparently caused an acute exacerbation of the rheumatic process. Purpura and a septic temperature developed. He began to cough and appeared dyspneic. He was put on sulfathiazole and digitalis medication but went progressively downhill, exhibiting a picture of cardiac decompensation. The patient died on May 10, 1941.

Postmortem examination showed myocardial hypertrophy with dilatation and a rheumatic aortic and mitral valvulitis.

CASE 3—D. K., a red haired boy born on July 6, 1931 and admitted to the institution on June 9, 1937, did not have cardiac abnormalities on admission or on periodic examinations. The child has had repeated admissions for infections of the upper respiratory tract. A systolic murmur without cardiac enlargement was elicited for the first time on Nov. 22, 1940 when the boy was admitted for acute tonsillitis. On March 5, 1941 during a periodic examination the boy appeared pale and short of breath. A double murmur was present at the apex, and the patient was hospitalized. He had a low grade fever and an

Fig. 4 (case 3)—Fluorogram illustrating left auricular enlargement. The heart is enlarged in the anteroposterior view with an abnormal contour. Passive congestion is present.

elevated pulse rate. The sedimentation rate was increased to 32 mm. He was discharged several months later but was readmitted in May 1941, at which time a routine examination revealed a pulse rate of 140 and a temperature of 102 F. He was acutely ill for two months, having a febrile course, a pulse rate averaging 140, persistent abdominal pain and repeated epistaxis. Since then he has had several similar exacerbations, the last one being in February 1942, at which time he showed evidence of cardiac decompensation (fig. 4). At present he has a to and fro murmur over the entire precordium, associated with cardiac enlargement and precordial bulging.

The remaining member of the family in the institution, a boy aged 9 years, recently had acute tonsillitis associated with arthritis of the left knee. He has a transient systolic murmur at the apex but no cardiac enlargement. Of the 3 children who are not in the institution a brother aged 21 was rejected from the Army because of "heart trouble" and a sister aged 16 complains frequently of leg aches.

COMMENT

In the temperate zones rheumatic fever occurs most frequently in the late winter and spring months. Young¹⁴ believed that the condition was more prevalent during periods of increased rainfall, while News-

¹⁴ Young, M. A Preliminary Study of the Epidemiology of Rheumatic Fever. *J. Hyg.* 20: 248 (Nov.) 1921.

holme¹⁵ associated a low incidence of rheumatic fever with heavy rainfall. We could not make a definite correlation between meteorologic conditions and the incidence of rheumatic fever. The influence of meteorologic conditions on the incidence of rheumatic fever seemed important so far as they might be related in exposing a patient to respiratory diseases, especially the hemolytic streptococcus infections.

An analysis of the symptoms and physical manifestations shows the peculiarities of rheumatic fever in childhood, such as the predominance of joint symptoms in the older children and carditis in the younger children. Abnormalities of the contour of the heart during a primary attack of acute rheumatic fever is rare except in cases of malignant involvement.¹⁶ The fact that 51 per cent of the children in our series showed abnormalities of the contour of the heart would indicate that many of the children had had previous attacks of rheumatic fever.

CONCLUSIONS AND SUMMARY

An epidemic of rheumatic fever in a children's school followed an outbreak of acute tonsillitis. Two hundred and forty-one children had acute hemolytic infections of the throat, while 88 children in the institution showed manifestations of rheumatic fever. The conclusion reached after studying various features of the epidemic are:

- 1 The epidemiology of rheumatic fever is closely linked with that of streptococcal infections of the upper respiratory tract.

- 2 Familial predisposition on the basis of specific tissue susceptibility probably is an important factor in the pathogenesis of rheumatic fever.

- 3 The most susceptible age group appeared to be between 9 and 14 years. Sex did not appear to be a factor.

- 4 Sixty-two children (65 per cent) had histories compatible with previous rheumatic infections. Sixty-one children had systolic apical murmurs elicited before the present rheumatic attack, most of them having the characteristics ascribed to functional murmurs. This would suggest that the murmurs should be observed repeatedly before they are dismissed as insignificant.

- 5 No direct correlation could be made between meteorologic conditions and the incidence of rheumatic fever. It was felt that they were important so far as they were related to the seasonal incidence of infections of the upper respiratory tract.

Decay in Medical Language—Over many years there has been progressive decay in the language of our profession. This is shown in different ways, and many factors produce it. Some of these undesirable elements deserve detailed comment because they are easily remedied. Medical idiom has deteriorated as part of a general decay in the English language in which the professional side shares. Lord Dunsany, an authoritative writer on this subject, attributes much of the decline to ignorance of the proper use of adjectives. To obtain vivid effect in writing particularly in the press, nouns frequently displace adjectives; thus 'a strange man in an expensive car' becomes a mystery man in a luxury car. The general effect of such a technique is to produce a disuse atrophy of many useful and descriptive words. In medical writing this is reflected in poverty of expression and lack of skill in clinical description. A few adjectival stalwarts are grossly overworked.—The Decay of Medical Language, editorial, *New Zealand M J* 41: 235 (Dec) 1942.

HYDRAULIC ABDOMINAL CONCUSSION

THE SYNDROME OF INTRA-ABDOMINAL UNDERWATER BLAST INJURY

LIEUTENANT COMMANDER LIONEL S. AUSTER
MC-V(S), U S N R

AND

LIEUTENANT COMMANDER JOHN H. WILLARD
MC-V(S), U S N R

Forces generated by underwater explosions incidental to marine disasters due to operations of war have produced physical injuries which we call the syndrome of "hydraulic abdominal concussion." The outstanding feature of this condition is the forceful compression of the abdomen simultaneous with the entrance of sea water into the bowel through the unprotected anus.

This phenomenon was first called to the attention of one of us (L. S. A.) in the winter of 1941 while in Iceland, where it was reported that following the submarine attack on and subsequent loss of one of our smaller naval vessels many of the personnel in the water were killed or injured by the explosion of depth charges carried on the deck of the sinking vessel with detonator mechanisms set for specific pressures. The sinking of the charges to the required depth caused the percussion plungers to become activated. Men in the water within a radius of several hundred yards were severely affected by the violent explosions.

MECHANISM OF INJURY

The now well recognized syndrome of blast injury of the lungs, first described by British observers and subsequently observed and studied by American physicians, following air raids involving high explosive bombing both at sea and ashore, has many features similar to the physical changes wrought by underwater blasts. In air blast the explosion produces what has been described as a sinusoidal sonic wave with alternating phases of compression and suction which may have a bearing on its frequently peculiar and freakish behavior. The pathologic changes are however usually the result of air compression on the chest wall with corresponding high pressure at the tracheal orifice causing alveolar rupture and interstitial hemorrhage in lung tissue and secondarily, probably as a result of venous back pressure, intracranial vascular accidents producing military to gross brain hemorrhage with resultant neurologic disturbances.

A depth charge is a steel drum containing several hundred pounds of high explosive with a suitable spring-plunger-trigger detonating mechanism which, when set for a certain depth, operates by water pressure developing on a constant scale as it sinks into the ocean. The explosion may give some manifestation in the air by blowing surface water up, but its chief effect is attained by the sudden commotion caused within a radius of several hundred yards. The surrounding water is set in motion in all directions producing currents powerful enough to weaken the seams of steel sheathed vessels within its zone of effectiveness. Men trapped aboard a sinking vessel or, more usually, those who have abandoned ship by going overboard clothed

in life jackets and swimming free or clinging to life rafts or bits of floating wreckage are subject to the water pressures generated. If the man is within a radius of 100 yards of the exploding charge the chances of survival are very slim, although we have seen cases in which a distance of less than 100 yards was reported with eventual rescue.

THE CLINICAL SYNDROME

The usual story is one in which the man, floating in the water, feels a sudden compression of his abdomen with sharp pain and a sensation of fullness followed by cramps. Either immediately following the blast or within half an hour several violently expulsive bowel movements take place with the passage of liquid stools into the sea. The man is usually surprised by this and, although the movements are not involuntary, they are nevertheless uncontrollable. Severe griping cramps are present and the performance may be repeated over a period of several hours. The man is frequently profoundly shocked and may be in a stuporous state, recovering spontaneously at varying intervals, floating about meanwhile in an aimless manner as a result of the efficient buoyancy of his life jacket. The following case is illustrative of the usual course of events.

CASE 1—After abandoning ship following torpedo hits, a seaman swam from the sinking destroyer and was about 200 yards from the fast disappearing hull, whose bow still showed when several blasts in quick succession took place under water. The disturbance in the water about him caused him to be submerged several times, and while being tossed about he felt a severe compression pain in his abdomen and lower chest which made breathing difficult. At the same time he felt an influx of sea water into his bowel through the anus, producing severe diffuse abdominal pain with a sensation of inordinate fullness. Without losing consciousness he nevertheless realized that for some minutes he was aimlessly floating about and could not control his direction. Some minutes later he began to have wavelike cramps in his abdomen similar to those following the administration of an enema and then had several urgent bowel movements in rapid succession followed by continuing intestinal cramps. He was in the water for about nine hours before being picked up and he was subsequently treated for shock, submersion and abdominal compression. He was considerably dehydrated. He maintained a moderate degree of bowel irritability for the next ten days, although his immediate reaction of pain, tenderness and spastic abdominal rigidity wore off within a few hours after being put to bed. No vomiting occurred and no further evidence of peritoneal irritation developed. He was well within two weeks after the incident.

Although this was a typical instance of mild reaction and course of the illness following acute hydraulic abdominal concussion there are many bizarre variations, some of which will be briefly detailed. On account of military restrictions the names, dates, places and details of identification are omitted in all these case reports. Although in most cases rather complete studies were made including blood, urine, spinal fluid and other laboratory examinations, there were many who did not receive complete x-ray and other studies because of the exigencies of the situation in which these patients were found. Some were treated at front line field stations, others at evacuation or base centers. The opportunity to perform complete scientific analyses was not always available or practicable, but all patients received the best clinical care and best therapeutic measures possible at the hands of a group of hard pressed, capable and enthusiastic, though often handicapped, medical officers.

Nausea and vomiting with signs of intraperitoneal irritation or injury frequently occurred. Such signs were usually accompanied by shock, the result of exposure and submersion, and sometimes of other injury either following shrapnel or bullet fire or trauma incidental to activity in leaving a sinking ship or blows from material in the water. The following case is illustrative.

CASE 2—A chief petty officer was thrown from the raft on which he had climbed, after abandoning his sinking ship, when the first "ashcan" went off. He was bruised on head and shoulder and had just managed to orient himself sufficiently to attempt regaining a hold on one of the hand lines when two more depth charges exploded in rapid succession at a distance of perhaps 150 yards, followed later by others with effects of less intensity. He was tossed about and felt a severe compression pain about his trunk and a sensation of forceful introduction of water into his bowel. After recovering his bearing he was unable to reach the life raft and floated about for about six hours before being picked up by rescue boats. He had an uncounted number of liquid stools while in the water, marked by great urgency and severe cramps. The nausea and vomiting, which continued for three days, did not begin until several hours after the blast incident and apparently had no relation to swallowed sea water, which was minimal.

He was treated for shock and submersion and contusions of the head and shoulder. The abdominal wall was rigid, painful and tender both on direct and rebound examination. Intravenous clises were regularly administered and only sips of water were permitted for several days. (Although operation was considered, no surgery was undertaken in view of the experiences with several other cases to be described.) Intestinal irritability was present for about a week and then gave way to constipation. At the end of two weeks the gradually diminishing abdominal tenderness and rigidity had disappeared, normal appetite had returned and during the next week the liberal administration of liquid petrolatum enabled the man to regain his former bowel habit. At the end of five weeks he was well, although he had occasional episodes of minor abdominal distress which were not disabling.

INTRA-ABDOMINAL PATHOLOGIC FINDINGS

The rescue of many of these men who, in addition to symptoms of shock and submersion, also showed definite signs of intra-abdominal injury with incontrovertible evidence of severe peritoneal irritation, posed a recurrent problem which required the exercise of delicate judgment. Unlike the experience of individuals immersed in the icy waters of the North Atlantic and the Arctic oceans, the warm temperatures of the Pacific near the equator permitted them to be afloat for periods of six to fifteen hours without the severe effects seen in colder regions although the effects of such prolonged immersion even in warm sea water should not be minimized. Some of these men did indeed suffer greater injury than ordinarily was expected, and the combination of underwater blast with submersion was unquestionably fatal for many whose bodies were not recovered as well as for those which were.

CASE 3—A postmortem examination performed on the body of a man who died while floating in the water after his ship was sunk revealed that, in addition to the multiple military hemorrhages throughout his bowel and several areas of grosser subserosal ecchymosis, he had also suffered a longitudinal tear in the ascending colon just above the cecum. The abdomen contained fecal material diluted with sea water, and evidence of early peritoneal inflammation.

CASE 4—A seaman brought ashore after a typical episode was in severe shock. Following his reaction from the experience, the persistence of abdominal pain, rigidity, direct and rebound tenderness of increasing severity and severe prostration

made operation imperative. It was found that he had a longitudinal tear in the transverse colon with overwhelming contamination of the peritoneum. Despite all efforts, he died.

CASE 5—Another seaman who had been afloat for about nine hours prior to his rescue exhibited incontrovertible evidence of intestinal perforation with peritonitis. At operation he was found to have a longitudinal tear in the upper sigmoid with early abscess formation. Exteriorization and drainage with supportive measures resulted in his subsequent evacuation, in a serious condition, but with good chance of recovery.

The findings in these and other cases at first seemed to indicate that early operation in all cases showing severe symptoms and signs might be indicated. Surgery was followed out in a number, some of which showed small pinpoint perforations, although the usual perforating lesion was a longitudinal tear in the colon at a distance from the anus and rectal ampulla. These were reminiscent of the tears seen in the practical joke injuries involving the application of compressed air outlets to the anus by workmen using air compressors with flexible hose attachments. There were, however, several instances of lesions involving the bowel wall without perforation which demonstrated that even in the absence of peritoneal contamination these patients did not do well following operation.

CASE 6—Following rescue after submersion with abdominal concussion, which occurred about twelve hours previously, a seaman had persistent severe abdominal symptoms which suggested peritonitis. At operation a careful search failed to reveal any evidence of perforation. The large bowel showed areas of milky petechial to macular subserosal hemorrhage with several areas of larger ecchymosis. Postoperatively, despite supportive measures and indwelling duodenal tube suction drainage, he became progressively worse and died.

CASE 7—A similar instance with almost identical findings was followed by a stormy postoperative course, and the patient eventually recovered.

CASE 8—Operation performed on a survivor who had been afloat for about eight hours following submersion and concussion with the usual story revealed a well sealed pinhead size perforation in the transverse colon in addition to the diffuse subserosal hemorrhages previously described. There were also occasional small areas of hemorrhage seen in the small intestine. The postoperative course was stormy and the patient showed definite evidence of toxicity with ileus, which was combated by indwelling continuous suction drainage of the intestine, intravenous infusions of plasma and electrolyte fluids, prostigmine and other measures. When evacuated, he was still in a precarious state.

THERAPEUTIC PROGRAM

Further experience demonstrated that, although there were some in which rents in the colon had occurred, most of the cases presenting pictures of persistent abdominal pain with signs of peritoneal irritation of lesser degree were cases of diffuse milky petechial and larger subserosal hemorrhage without perforation. Despite the universal use of intra-abdominal sulfanilamide, suction drainage, plasma, saline and dextrose infusions, prostigmine and morphine and all other means of support, these patients invariably had a disturbing postoperative course and in some instances died. A change in therapy with emphasis on the expectant and supportive features of the program resulted in a more generally successful outcome.

CASE 9—A chief petty officer had been subjected to four or five underwater blasts at a distance of about 200 yards after leaving his ship and had numerous bowel evacuations with persistence of cramps over a period of about nine hours, after which time he was rescued. His course was marked for the next few days by recurrent waves of colic with diffuse peritoneal irritative signs, abdominal distention and occasional

vomiting. Morphine, indwelling continuous intestinal suction drainage and concomitant intravenous infusions for three days resulted in subsidence of acute symptoms, although tenderness and rigidity persisted for about ten days. Fourteen days after the episode he felt well and his appetite improved, although dietary indiscretion still precipitated abdominal discomfort. Constipation of mild degree required liquid petrolatum for regulation of bowel habit. No blood was ever found in the later stools. (Examination in the early stages of his illness was not made, although there were never evidences of gross bleeding.)

CASE 10—An ensign who had had severe underwater blast concussion with the usual train of symptoms had persistent abdominal discomfort and cramps for several days with signs of peritoneal irritation and distention. Treatment with indwelling continuous intestinal suction drainage, infusions and morphine resulted in recovery from immediate symptoms and signs in about four days with subsequent recurrent intestinal irritability and occasional cramps with diarrhea during the next two weeks.

CASE 11—A petty officer who had run the usual course of underwater blast injury with subsequent epigastric distress, rigidity, peritoneal irritation and vomiting was similarly treated with success. Fourteen days after the episode he had recurrence of symptoms with vomiting and high abdominal pain and distention. Indwelling tube drainage was successful in relieving the situation in twenty-four hours. A second recurrence about a week later indicated the presence of adhesions causing partial jejunal obstruction, which was again easily relieved by the passage of a Levin tube with suction drainage for twenty-four hours. This man apparently had had a small perforation in addition to the subserosal hemorrhage in his bowel, and the later course of the healing process with omentum sealed over it caused the development of a kink or torsion which gave rise to intermittent obstruction. He was evacuated and his subsequent course is not known, although he was momentarily well at the time of his departure.

These cases are illustrative of the general pattern of clinical course and therapy followed in the greater number of instances. The conservative program with symptomatic therapy proved to be the most successful. Instances of major perforation, however, were of necessity treated by operation. Decision concerning these was often difficult and the outcome unsatisfactory.

COMPLICATIONS

With realization of the pathologic changes under way in the bowel, chiefly the development of smaller and larger areas of subserosal and mucosal hemorrhage, it was inevitable that some later manifestations of these mural injuries should become apparent. Peritoneal reactions to the serosal injuries undoubtedly account for most of the acute abdominal symptoms and signs which were outstanding in the immediate course of these patients' illnesses. Symptoms of colitis are obviously understood also. Unfortunately, apparatus for proctosigmoidoscopy was not available at the time most of these patients were seen and therefore the appearance of the mucosal surface of the lower bowel in life was not observed. It was expected, however, that there should be evidence of intestinal bleeding, and fecal examination for blood revealed positive findings in several instances. One case of gross bleeding, probably due to late ulceration of an area of intramural hemorrhage, is of interest.

CASE 12—A junior officer who had six or seven loose movements within a period of about twenty minutes subsequent to his abdominal concussion was also suffering from a severe laceration of the scalp when he was rescued four hours later. His intestinal symptoms were limited to mild cramps and abdominal tenderness, which persisted for three days. On the tenth day of his hospitalization for treatment of the scalp wound, just prior to discharge to duty, he was awakened in the

morning by colic, which was relieved by a large soft stool. This was followed within half an hour by another liquid movement, after which he fainted. It was found that he had passed a large quantity of bright red blood. He was kept at rest for three days with sedation and no further evidence of bleeding developed. This hemorrhage was probably the result of rupture into the bowel of a large hematoma in the interstitial tissues of the sigmoid following mucosal ulceration.

The variability of the forces operating in underwater explosions have given rise to effects other than direct intestinal concussion. Sudden compression of the abdominal wall against resistance has produced injury simulating traumatic hernia. Examples of inguinal and diaphragmatic locations of these follow.

CASE 13—Following the abandonment of his ship, a petty officer was subjected to hydraulic abdominal concussion when the depth charges exploded after the stern of the vessel sank, the bow having previously been blown away from the ship. After several liquid bowel evacuations in the water he swam toward and eventually reached the bow of the vessel, which by virtue of its compartmentation and buoyancy remained afloat after the remainder of the ship had gone down. He climbed aboard by an anchor chain and remained there through the night until rescued some six hours later.

In addition to intestinal irritability and abdominal pain and cramps he had a diffuse swelling, sausage shaped and tender, occupying the right inguinal canal, the right spermatic cord and the tissues about the right testis. This was interpreted as being a traumatic hernia, treatment of which could not be undertaken at the time on account of the man's general condition and the lack of surgical facilities at the moment. Since he seemed to improve within the next few days he was watched and subsequently evacuated to a nearby base where, two weeks after the incident, he was operated on for the persistent lump and infiltration in his inguinal canal and cord. Recurrent bouts of cramps, pain referred to the right groin tenderness and two to three loose stools daily gave clinical confirmation to the impression that this was a traumatic hernia with incarceration of a piece of omentum in the sac. There was also a fading area of ecchymosis involving the surrounding inguinal and femoral skin. Operation with careful dissection of all layers of inguinal area, cord and tunica failed to reveal a patent sac, the entire area being involved in a hemorrhagic plastic inflammatory process with the region in and about the internal ring sealed off tightly in a smooth manner. Inflamed thickened tissues were dissected free and resected. The abdomen was not opened. Bassini repair was made and healing was uneventful. Bowel irritability continued for a week before it subsided. He was evacuated as a convalescent.

CASE 14—After the subsidence of the acute symptoms of hydraulic abdominal concussion this man persisted in having recurrent symptoms of high epigastric discomfort, indigestion and occasional vomiting. Physical examination elicited moderate tenderness on deep pressure in the epigastrium and unusually high tympany in the left lower chest. X-ray examination revealed the presence of the colon and distorted stomach in an unusually high supradiaphragmatic position in the left thorax, interpreted as diaphragmatic herniation of abdominal viscera. He was evacuated for further study and treatment.

The sequelae of underwater blast injury have not always been as simple or apparent as these. There have been some instances of delayed complications and involved series of clinical events which have taxed the interpretive and therapeutic ingenuity of medical officers in attendance. The following is illustrative.

CASE 15—Following severe hydraulic abdominal concussion this man had a stormy course marked by high abdominal distress with vomiting. Under conservative treatment the condition seemed well controlled until about a month after the episode, when he became worse with symptoms of high obstruction, vomiting, deep epigastric pain and collapse. Clinically he appeared to have diaphragmatic hernia with constriction, over night, under adequate sedation and gastroduodenal tube

drainage, the condition was relieved and x-ray examination failed to reveal presence of abdominal viscera in the thorax, although the splenic flexure and stomach were high in position under the left diaphragmatic leaf. Within the next few days the moderate fever became higher, deep epigastric pain extended to the lower substernal region and giddiness, cerebellar ataxia and semistupor developed. A week later purulent expectoration appeared. X-ray evidence of a small zone of pneumonitis in the lower medial area of the left lower lobe was suggestive of early abscess formation. The subsequent course was marked by further development of signs and symptoms indicative of lung abscess and questionable intracranial process interpreted as brain abscess, although there were no localizing signs.

This case probably represents an instance of injury with perforation into or adjacent to the mediastinum, mediastinal inflammation with eventual involvement of adjacent lung progressed to abscess formation and secondary cerebral pyogenic metastasis. The intracranial process may also have been the result of hemorrhage caused by venous backpressure incidental to the external pressure developed by the explosion similar to that seen in air blast injury to the lung in bombing by aircraft.

It has been a source of wonder to us that there have been so few instances of intrathoracic compression injury seen in association with hydraulic abdominal concussion. Aside from a case of empyema thoracis reported to us by Lieutenant Commander Marvin Overton which he saw in a Japanese prisoner who had been in an incident of underwater blast 2 cases of fatal pulmonary edema marked by bloody froth following similar experiences reported by Lieutenant Commander Edwin Steele and 1 case of intrathoracic injury with bloody pulmonary edema seen by Lieutenant Commander Albert S. Hyman, we know of no examples of direct pulmonary damage resulting from hydraulic concussion. It is undoubted that there have been instances of intrathoracic damage either by direct violence or by aspiration of seawater incidental to the marine disturbance. Many men have been lost at sea following these incidents. Survivors have, we believe, been protected by the natural resistance and resilience of the thoracic cage reinforced and protected by the thick kapok life jacket which has been worn by all those who have been rescued. This is a different mechanism than that producing blast injury in the air and should not be confused with it.

COMMENT

The name "hydraulic abdominal concussion" is given to a syndrome of intra-abdominal intestinal injury resulting from underwater explosions with compression of the abdominal parietes against resistance from water which has entered the lumen of the bowel through the weak anal sphincter. "Hydraulic" refers to the forces of water in motion. "Concussion" is used in preference to the word "compression" or any other descriptive word because we feel that the results of this unique accident are similar to those which occur in the brain or other tissues when subjected to sudden force against resistance. This upsets the equilibrium of the part and produces a molecular, cellular or tissue commotion or disturbance demonstrable as injury by interstitial hemorrhage of varying degree up to gross solution of continuity of the tissue itself.

There have been numerous instances of this occurrence, several illustrative cases of which have been briefly described. The usual course of events is one in which a man finds himself in the sea after abandoning ship following a naval engagement, he is within a radius of 100 to 300 yards when one or more depth charges explode under water, forceful water currents are generated, producing external abdominal compres-

sion simultaneous with the entrance of sea water into the bowel through the anus. Within half an hour there are usually three to ten fluid bowel movements accompanied by violent cramps in the attempt of the bowel to rid itself of the irritating bulk of strongly hypertonic salt water. Dehydration and shock are common. Bowel irritability, with more or less repetition of the fluid stools, continues for several days and sometimes for two weeks.

Examination of the abdominal contents at operations performed in cases characterized by severe peritoneal irritation have shown the chief lesion to be milary, discrete and confluent, subserosal and mucosal intestinal hemorrhages with frequent appearance of larger areas of ecchymosis and hematoma which must inevitably involve the mucosa to a greater or less degree. The serosal irritation produces the peritoneal signs. The breakdown and tension about larger areas of intramural hemorrhage and the damage to mucosa have produced evidence of minor and major intestinal bleeding. We believe that the late results of these injuries may vary from nothing at all to the full blown picture of active or healed ulcerative colitis. It is suggested that these possibilities be kept in mind for future reference in cases with a history of hydraulic abdominal concussion.

The relatively rare examples of macroscopic perforation seen provoke some speculation. In those patients whose intestine was seen at operation it was unusual to see involvement of small intestine in other than scant milary subserosal hemorrhages. The lesions were always chiefly in the colon. No cases of small bowel perforation were seen, the ileocecal valve apparently acting as an efficient barrier to pressure from below. Rents in the large bowel were either pinpoint or longitudinal. They were all at a distance from the rectum, and we believe that their occurrence depends on a combination of factors including degree of pressure both within and without the bowel lumen, and the amounts of fecal material and of gas present at the time. We gain the impression that most of these perforations are the result of "blow outs" at a point where a bubble of gas compressed from below meets an obstruction. Only this will explain the occurrence of leaks in the cecal area and transverse colon. The longitudinal nature of the rents is consistent with the anatomic weakness in structure found in the colon in this direction.

Treatment of these injuries requires good judgment and, at times, considerable courage to withhold operation in the face of what may seem to be an urgent abdominal emergency. They are, in fact, all urgent abdominal emergencies, but experience has shown that supportive treatment without operation produces the best results. Manifestations of frank major perforation of course are indications for operation. Despite all our modern technics and even with the invaluable support of chemotherapy, the mortality in such cases is unusually high and apparently unavoidable. Treatment of small perforations and the peritoneal inflammatory reactions secondary to intramural intestinal hemorrhage and concussion has been most successful with morphine, indwelling intestinal suction drainage and intravenous infusions of electrolyte, dextrose and plasma.

This report is published in the hope that others who may have the occasion to see similar cases will be enabled to recognize the lesions and, if their facilities warrant, may be stimulated to make further observations of a more extensive and accurate nature than we have done.

TREATMENT OF EPIDEMIC KERATO- CONJUNCTIVITIS

PRELIMINARY REPORT OF TEN CASES

ALSON E. BRALEY, M.D.
AND

MURRAY SANDERS, M.D.
NEW YORK

Epidemic keratoconjunctivitis (shipyard conjunctivitis) was reported on the west coast in 1941 by Hogan and Crawford¹. The disease began to appear on the east coast in 1942.² Although a few short notes suggesting therapy have appeared, it has been generally conceded that no treatment either local or general has materially shortened the course of the disease.

Reports received from the Middle West indicate that the disease is now appearing in parts of this important industrial area. Although the present preliminary report on therapy is based on a small number of cases and has not been controlled, the exigencies of a new infection in wartime industry for which no treatment is known warrant publication of therapeutic studies which may be of some assistance to physicians. Controlled groups are being studied and reports will be published later, along with detailed data on potencies of the serums used.

The studies of one of us (M. S.) have shown that blood serum from persons recovered from the disease contains a substance which will neutralize the virus in mice. We have seen that blood serum of recovered patients gradually builds up a titer of protective substance after the conjunctival phase of the disease has disappeared. Attempts were made, therefore, to draw the blood of convalescent patients when this titer of neutralizing substance was highest.

In an epidemic studied in cooperation with the New York State Public Health Department corneal changes developed in 85 per cent of the cases.³ The fact that not all cases showed corneal changes indicated that there is either a milder form of the disease in which conjunctivitis alone appears or that mistakes were made in the diagnosis of these cases. The former seemed the more likely in the face of an epidemic. When any form of treatment is to be used some form of case selection must be carried out in order to eliminate the mild forms and the instances of mistaken diagnosis.

All cases reported here presented the following manifestations:

- 1 Pronounced edema of the lids, conjunctiva and a semilunar fold with bulbar chemosis
- 2 Preauricular lymph node involvement, usually submental, and anterior cervical as well
- 3 Severe ocular discomfort associated with excessive tearing
- 4 Conjunctival scrapings containing only mononuclear cells and practically no polymorphonuclear leukocytes
- 5 Negative cultures

From the Department of Ophthalmology, Columbia University College of Physicians and Surgeons.

Aided in part by grants from the John and Mary R. Markle Foundation and the Warner Institute for Therapeutic Research.

Released for publication by the War Department Manuscript Board which assumes no responsibility, other than censorship for the contents of this article.

This investigation was carried on in informal collaboration with the Commission on Neurotropic Virus Diseases, Board for the Investigation and Control of Influenza and Other Epidemic Diseases in the Army.

¹ Hogan, M. J. and Crawford, J. W. *Am. J. Ophth.* 25: 1059 (Sept.) 1942.

² Sanders, Murray. Epidemic keratoconjunctivitis. *Arch. Ophth.* 28: 581 (Oct.) 1942.

³ Perkins, J. E., Korns, R., and Westphal, R. Unpublished data.

Typical corneal changes were present in 4 cases and probable corneal changes in 2 additional cases.

With these criteria as a guide, it seemed that the most likely diagnosis was epidemic keratoconjunctivitis. In 4 cases a definite history of close contact with a known case of epidemic keratoconjunctivitis was given. Two of these patients had no corneal involvement when first seen.

CASE 1—G T, a physician not acquainted with this disease, was seen on the tenth day after onset of severe bilateral epidemic keratoconjunctivitis. He gave a history of having seen a man in his office about two weeks before who complained of a sensation of a foreign body in the eye. The physician was unable to find the foreign body but stated that the man had chemosis and edema of the upper lid. Subsequent investigation proved that this man had epidemic keratoconjunctivitis. G T had lid edema, chemosis, follicular hyperplasia and involvement of the preauricular lymph node and of the cornea of the left eye. His vision was only 20/200 in this eye. On the tenth day 50 cc of plasma was given intravenously from R B (this patient had a titer of 10,000 neutralizing doses and had many corneal changes). Twenty-four hours after administration of the intravenous plasma G T was much improved but still had

Case 6 is of interest but could not be carefully followed.

CASE 6—J S had severe involvement of the left eye with beginning corneal changes. He was given 40 cc of potent convalescent serum intravenously on the seventh day of the disease. The following day he stated that he was symptomatically improved, but the follow-up from then on could not be carried out. His physician reported subsequent involvement of the other eye with typical corneal changes in the first eye.

Treatment in this case is classed as a failure, but opinion should be reserved until further check-up can be made.

All cases are reviewed in the accompanying table. Seven patients were clinically cured. In 2 cases the normal course of the disease was shortened and corneal changes possibly were aborted. One case is classed as a failure because of inadequate follow-up.

COMMENT AND CONCLUSIONS

The present widespread occurrence of epidemic keratoconjunctivitis in important industrial areas and the failure of all types of therapy justify the focusing

Results of Convalescent Serum Therapy in Ten Cases

Case	Name	Days After Onset	Contact	Involvement of		Titer of Protective Substance of Convalescent	Titer of Serum	Amount of Serum Given, Cc	Result
				Conjunctiva	Cornea				
1	G T	10	Saw patient with disease	4+ both eyes	2+ left eye	10	10,000	40	Few half moon corneal opacities
2	M T	3	Husband	4+ both eyes	0	0	10,000	40	48 hour clinical cure
3	B T	2	Father	3+ right eye	0	Not done	10,000	20	48 hour cure
4	M N	5	Unknown	4+ left eye	0		10,000	40	48 hour cure
5	A S	6	Unknown	4+ both eyes	+ right eye 60+	0	10,000	30	Two small corneal opacities right eye 48 hour conjunctival cure
6	J S	6	Patient	4+ both eyes	+ left eye	0	10,000	40	24 hour much improved 48 hour nearly cured 72 hour recurrence?
7	D S	4	Unknown	4+ both eyes	± left eye 0 right eye	0	1,000	10	Slow recovery 72 hours half moon corneal changes left eye
8	J L	7	Unknown	3+ both eyes	+ left eye 0 right eye	0	10,000	20	24 hour much improvement 48 hour cure
9	H T	5	Unknown	3+ both eyes	± left eye 0 right eye	0	1,000	50	48 hour cure no corneal change
10	M F	4	Unknown	4+ right eye	0	0	10,000	40	48 hour cure

moderate edema and corneal changes. The following day the edema was gone and all that remained were follicles on the conjunctiva and typical corneal changes. Four days later his vision was 20/30 and he stated that he was cured. Examination of the cornea showed small half-moon shaped opacities where previously there had been large round subepithelial opacities. These have remained almost stationary but his vision has improved to 20/20.

CASES 2 and 3—M T and B T, the wife and 10 year old son respectively of physician G T, presumably had primary contact with him. They were seen on the third and second day of the disease respectively. M T had a severe and bilateral form of the disease but no typical corneal involvement. B T had moderately mild and unilateral involvement. M T received 40 cc of convalescent serum and B T 20 cc. Both were clinically cured in forty eight hours.

Case 7 is of considerable interest

CASE 7—D S, a woman, also a physician was not known to have had any contact with the disease. We were able to obtain only 15 cc of convalescent serum, the potency of which was only 1,000 neutralizing doses. She had a severe involvement of the left eye but no corneal opacities when first seen. The 15 cc of serum was given on the fourth day of the disease, and there was slight improvement. On the sixth day the second eye became mildly involved. Her improvement was slow, but by the eleventh day the conjunctiva of each eye was quite normal. The left eye showed very thin half-moon shaped subepithelial opacities. These have remained almost stationary

of attention on the use of convalescent serum as a possible means of treatment. In the present group of 10 cases, 9 showed striking clinical improvement a short time after intravenous injections of human convalescent serum were given. However, need for a controlled group of cases cannot be stressed too strongly. It has been pointed out⁴ that there is no correlation between the intensity of clinical symptoms and the duration of the disease. It should also be remembered that it is highly desirable that the present study be enlarged, from the point of view both of treated and of control cases, and that standard, accurately titered convalescent serums be employed.⁵

⁴ Sanders, Murray, Culliver, F. D., Torchheimer, L. L., and Alexander, R. C. Epidemic keratoconjunctivitis. J. A. M. A. 121: 250 (Jan. 23) 1942.

⁵ Since this report was written 10 additional patients have been treated: 8 with convalescent plasma and 2 with normal plasma. In each instance 50 cc was injected intravenously. The 2 patients who received normal plasma followed the usual course of the disease. The first patient still has corneal opacities after two months and the acute inflammation lasted for five weeks. The second patient also has corneal opacities which are still present and the course of the acute disease lasted three weeks. The 8 patients who received convalescent plasma were treated on the second to the fifth day of the disease. One of these patients developed corneal opacities and the clinical course of the disease was shortened from two days to one week. Oddly enough 1 of the patients whose clinical course was shortened to three days developed a few corneal opacities on the fourteenth day. We are still encouraged with the therapy.

STANDARD NOMENCLATURE OF DISEASE AND STANDARD NOMENCLATURE OF OPERATIONS

EDWIN P. JORDAN, M.D.
CHICAGO

The first edition of the portion of this nomenclature covering disease, under the editorship of Dr H. B. Logie, appeared in 1932. It was developed as the result of a national conference on nomenclature of disease initiated by invitation of the New York Academy of Medicine, March 22, 1928. A number of subscribers, special funds, insurance companies and medical organizations supported this work. A second edition appeared in 1935.

In 1937 the editing and publishing of the book was undertaken by the American Medical Association. The preparation of a third edition was begun at once. In connection with this revision a fourth national conference on medical nomenclature was held under the auspices of the American Medical Association in Chicago, March 1, 1940, with Dr. Haven Emerson of New York serving as chairman. About sixty delegates from interested organizations and institutions attended that conference, the proceedings of which were abstracted in *THE JOURNAL*, May 18 and 25, 1940. The conference agreed that in the intervals between national conferences the work of the Standard Nomenclature should be under the direction of the editor and an editorial advisory board. The present editor is Dr. Edwin P. Jordan and the members of the board are Drs. Dana W. Atchley, George Baehr, Bowman C. Crowell, Neil A. Dayton, Halbert L. Dunn, James R. Miller and Christopher G. Parnall.

The primary purpose of this classification of disease is educational. By clearly differentiating between a disease and its symptoms and by canalizing thought along lines of location and etiology this system tends to improve rational understanding of disease. Eponyms and many terms which have been carelessly employed in the past have been largely eliminated.

The Standard Nomenclature of Disease aims to include every disease which is clinically recognizable and to avoid repetition and overlapping. English terms when in good usage have been preferred to Latin or Greek terms. There have been, however, many exceptions. A clear distinction has been drawn between a disease and the manifestations or symptoms which it produces. The method of classification has been designed primarily for clinicians and not for pathologists, roentgenologists or workers in other special fields. Its uniformity and other features make it readily adaptable to serve as a source for information on the distribution and prevalence of disease.

The method of classification followed is based simply on two primary factors: the portion of the body involved (topographic) and the cause of the disorder (etiologic). The topographic features are designated by numerical digits separated from the etiologic factors by a hyphen. The first three digits in the disease code describe the topographic site, the last three following the hyphen, describe the etiologic agent. The digits are uniform throughout the classification according to a key.

The new edition appeared in June 1942. The nomenclature of disease has been simplified in some ways; the diagnoses which are likely to occur with relative

frequency in hospital practice have been placed in bold-face type; there is a new introduction giving instructions to medical record librarians in the use of the nomenclature; the index is entirely new and has been designed to facilitate access to the proper diagnostic term; there is a new table of eponymic diseases which serves as a supplementary index; and there is new thumb indexing.

There has long been a demand for a nomenclature of operations to parallel and accompany the Standard Nomenclature of Disease. This new nomenclature of operations (bound with the nomenclature of disease) has been prepared by the Committee on Operative Nomenclature which was authorized by the National Conference on Medical Nomenclature. The Committee consists of Dr. H. Perry Jenkins, chairman, and Drs. T. R. Ponton and Bronson S. Ray, each of whom has had wide experience in the field. Topographic numbers in this classification, like those digits appearing before the hyphen, correspond exactly with those used in the Standard Nomenclature of Disease. The fundamental surgical procedures—the key—are expressed by digits following the hyphen. There are nine fundamental surgical procedures: incision, excision, amputation, introduction, endoscopy, repair, destruction, suture and manipulation. These main operative procedures have been further subdivided. The classification has been developed by employing the digits specifying the anatomic structure operated on and the posthyphen digits specifying the exact operative procedure. This arrangement follows the same topographic principles as those employed in the nomenclature of disease; the different types of operations are found under the specific organs or regions involved. It is believed that this is as complete as necessary for the use of the average general hospital. There is of course a separate index to the nomenclature of operations. A supplementary classification of anesthetic agents and methods accompanies the nomenclature of operations.

The previous editions of the disease nomenclature have been widely employed by leading hospitals throughout this country and Canada as well as abroad. The system of classification is applicable to small as well as to large hospitals. It is believed that the simplifications introduced and added directions make this edition less formidable and that the addition of the Standard Nomenclature of Operations makes this presentation more complete.

535 North Dearborn Street

Nervous Indigestion—Nervous indigestion means precisely what it implies, namely, a digestive disturbance which is mediated through the nervous system. Ordinarily we speak of nervous indigestion as a disturbance which is brought about by those nervous factors which impair the adaptability of the individual to his surroundings. The individual, as a member of society, is subject to forces many of which are beyond his control. Some of these arise in his home life or derive from marital adjustments, economic factors or stress and strain from a thousand different sources, small in themselves but accumulating to produce widespread nervous aberrations. Today the problem of nervous indigestion is perhaps one of the commonest that the medical man is called on to treat. There is no reasonable doubt in any one's mind that the factors and forces today which are abroad throughout the land can bring about severe dislocation in the smooth function of the autonomic nervous system and result in what is perhaps the commonest of all complaints—nervous indigestion.—Rehfuess, Martin E. *Indigestion: Its Diagnosis and Management*. Philadelphia: W. P. Saunders Company, 1943.

THE EMPLOYMENT AND PLACEMENT OF HANDICAPPED PERSONS IN INDUSTRY

HARVEY BARTLE, M.D.

PHILADELPHIA

Greatly increased attention has been given recently to the employment and placement of handicapped persons in industry. Profit psychology and profit minded factors are no longer justifiable motives for continuing past practices which are fast becoming outmoded, that of accepting the "one hundred per cent" physically and mentally fit to the exclusion of all substandard individuals. This discriminatory attitude has been condemned loudly and frequently by the handicapped themselves and by others interested in the progress of social welfare. The competitive spirit in industry has not permitted great departure even yet from long established principles, and many employers continue to believe that the engagement of handicapped persons immediately creates an imbalance in production. This decreased production, from an economic standpoint, gives an unfair advantage to a competitor. On the other hand labor and welfare groups claim that handicapped persons, if excluded from employment in industry, create a class of unemployed and unemployable persons to whom society must of necessity render assistance. The financial support necessary to discharge this responsibility must eventually be derived from industry, directly or indirectly.

Shall industry engage handicapped persons and thus absorb them as a direct responsibility, or shall assistance be given through other channels the expense of which will be an indirect responsibility on industry? A workable plan for an equitable distribution of responsibility for engaging and integrating the large group of willing but handicapped workers will be a tremendous task to avoid hardship on employee, employer and industry. Whether this can be accomplished by a voluntary effort on the part of all industries by a mutual pact or understanding remains to be seen. This would be preferable to state enforcement through legal enactment. There are many factors in a discussion of this character necessitating further elaboration.

There has been in recent years a change in social thinking, resulting in a new concept of personal social security. There is sure to appear eventually a definite pattern or program to accomplish social security in a practical workable manner. The scheme will not only involve working days, hours and per diem rates of pay but will plan to assist handicapped persons in securing remunerative work rather than continuing them as beneficiaries of relatives, friends or welfare associations. If industry does not cooperate in this suggestion, the alternative "the survival of the fittest" naturally follows.

When industrialists are convinced and have a mind to face the issue squarely, a plan will be forthcoming which will represent the parallel interests of employer and employee. The economic feature under this caption, from a personal aspect, has many implications. It is also a real problem to the production manager in many job placements. There is, however, at this time, on account of the war, an overriding demand to use

to the fullest extent all manpower available. The prodigal labor supply of yesterday is now supplanted by an appalling scarcity. The only criterion at present is Can the person produce? Logically, if the handicapped can produce he should be employed, if employed he becomes a wage earner and a self-respecting member of society.

Industry bluntly and pertinently asks "Will it work?" Safety is an important consideration in placement so as not to jeopardize the person's life or aggravate his impediment. This is not only a humane question but an intensely practical one. An appraisal of the physical and mental status of the interested person should be made by a physician and become a matter of record to guide the supervisor in industry and later for comparative purposes. Will the placement of handicapped persons jeopardize lives and property of other persons? A potentially unsafe person, who may jeopardize life and property, is a menace not to be condoned. The appraisal of the physical and mental status on which an opinion can be predicated is important. In the final analysis the service rendered by the handicapped person must be weighed against the other factors involved.

The eyes present an interesting and widespread problem to the industrial physician and placement supervisor. The abnormalities range from simple refractive errors to muscle imbalance and serious and complicating disturbance of the inner structures of the eye. Blanket approval or disapproval of persons should not be assigned without considered judgment in each case. Specialists in this field have contributed greatly to the benefit of the employee and employer, in retarding eye deficiencies and advancing corrective measures to reduce to a minimum the dislocation of workers. Deficiencies in color perception will obviously interfere with placement in some textile fields, in work handling multi-colored wires in cables, in transportation where it is necessary to observe colored signals and in other fields in which acute color perception is essential. It need not hamper persons in general industrial work.

Eye refractions to correct vision, general health measures to correct or retard disease of the eyes, and finally placement to obviate the demands of close application or other eyestrain completes the threefold approach to handling and disposing of handicapped persons falling within this category. The results obtained by follow-up supervision of workers with eye defects is an inspiration and fully justifies the advisability of the program.

Deficient hearing is an impediment in placement. While artificial hearing devices may improve the hearing they are not fully reliable under all circumstances. The transportation industries have rather high requirements in vision and hearing. There is certainly no reason to deny persons with deficiencies in hearing and vision from all classes of work.

The tuberculous person of the chronic pulmonary type in a quiescent state is safe to mingle with others provided there is assurance that no activation exists. Placement of such persons in well ventilated work rooms with medically controlled assignments requiring minimal physical effort is permissible. For instance, a few decades ago the medical dispensaries referred quiescent tuberculous patients for work on the street cars, which was essentially outside work where a minimum amount of physical effort was required. This placement was in reality a therapeutic measure in rehabilitation.

Many tuberculous persons employed in suitable jobs react favorably and do effective service under proper

industrial medical supervision. Routine periodic x-ray examination, sputum analysis and clinical examination to safeguard patients and contacts properly are of course highly essential.

Diabetes is not necessarily a cause for displacing an employee. The diabetic patient requires dietetic advice and urine and blood sugar evaluation routinely. In hazardous work the diabetic person who uses insulin regularly must be given special attention concerning placement.

A patient with heart disease, with good compensation, may do well in special placements which do not require physical effort sufficient to aggravate the crippled heart.

In the average stable industry there are about 8 per cent of the entire personnel who are cardiac patients. This group of trained artisans need not and should not be discarded. With proper medical supervision they can continue in active service, with shifting of placement and general oversight, for many years without shortening or jeopardizing life. This group does not include the many persons who die suddenly of a heart attack who previously have shown no symptoms referable to the heart.

The patient with kidney disease may be appraised and the person's usefulness continued under proper guidance. Examination of urine and possibly of blood at regular intervals will be necessary.

Syphilis should be discovered, evaluated and properly treated and its transmissibility definitely stated. The determination of the employability of those afflicted should be predicated on knowledge, capable supervision and safety.

Arthritis varies in its ability to incapacitate from mild joint pain to complete crippling. It is obvious that placement will play an important role among the arthritic. It requires reason, sympathy and good common sense to adjust the needs of both the handicapped and industry.

Persons recovering from fractures of all types and victims of severe or mutilating injuries require special consideration. These anatomic changes, while handicapping the victims, may not impair general health. There is a limited sphere of placement open to those who have lost one or more limbs. Nevertheless, if there is a "will to do" industry may profitably place them. It is a particular achievement to secure cooperation in the case of the tragic back injury or post-traumatic neuroses. In back injuries, x-ray reports should be a matter of record not only to guide the afflicted person but to prevent him from being misguided.

A conspicuous group of handicapped individuals are the nervous and mentally sick. In making health appraisals the mental aspect has been grossly neglected. Present day emphasis will throw new light and attention on neuromental states. The placement of these persons requires serious thought in evaluating capabilities and available supervision. Those mildly afflicted are capable of a normal work output under proper supervision and environmental influence. Unfortunately, some industries cannot open their doors to persons who have been mentally ill. The placement of quiescent cases of dementia precox, manic depressive insanity and dementia paralytica is a debatable subject and is contingent on safety hazards, need for close application to the job, judgment and facilities for observation and supervision over these workers.

In the gradual progress of industrial medicine and surgery through the years there has been developed an art and science in evaluating, treating and placing injured persons. A sympathetic approach, good remedial medical service and considered placement accomplish the best results.

CONCLUSION

The full utilization of all manpower is necessary to keep production at a maximum. Adjustment to achieve this objective for the handicapped should include non-hazardous placement, postural therapy, sitting instead of standing, work in which eye strain is not demanded, deliberate work avoiding the highly repetitive operations for the nervous, and a great number of other factors arising in many and varied industries.

THE HOSPITAL PHARMACY

AUSTIN E. SMITH, M.D.

Secretary, Council on Pharmacy and Chemistry
CHICAGO

The hospital pharmacy should be a diplomatic door to rational therapeutics in hospital practice. As one of the most frequently consulted therapeutic departments, it is in intimate relation with the hospital administrators, attending physicians and nursing staff. The influence which it can exert over the purchase and dispensing of drugs is often overlooked.

Five principles have been proposed for an adequate pharmacy service in the hospital: the organization of a hospital pharmaceutical service, the appointment of a pharmacy committee, the maintenance of a pharmaceutical reference library, the use of standard preparations and adequate supervision. In determining the policy of operation, the pharmacy committee should recommend only the use of official agents and nonofficial drugs which have been evaluated by competent medical bodies. Informative standards are the United States Pharmacopeia, the National Formulary and New and Nonofficial Remedies, publications of bodies which have been chosen as representative of pharmacy and medicine.

The economy of choosing drugs judiciously has been demonstrated repeatedly. One hospital pharmacy experienced a saving of \$50,000 within one year after the adoption of specific regulations by the hospital formulary committee, this saving being effected essentially by the limiting of the number of drugs with similar therapeutic action, the elimination of unnecessarily complex mixtures and the regulation of proprietary drugs.

Although a pharmaceutical manufacturer is entitled to the rewards due from the discovery of a new and useful drug, the purchasing department must recognize the economic loss of buying proprietary preparations when official equivalents are available. There is almost always an appreciable difference in the costs. For example, a survey of the September 1941 issue of a popular price list of drugs revealed that the total cost of an ounce of each of nineteen substances under a protected name was \$48.67, whereas the total cost of an ounce of each of these substances under an unprotected name was \$15.67. Thus the cost of a proprietary name to the consumer would be \$33. Included in these nineteen agents were sedatives, vasoconstrictors, local anesthetics, anti-infective agents and analgesics.

In 1933 Hatcher and Stansby proposed eight rules to aid a hospital formulary committee in determining the admission of articles. These rules are still admirably applicable and in part declare simple official (Pharmacopoeial) substances may be admitted on request unless they have become superfluous, no article should be admitted, except for controlled research, before its therapeutic value has been established, no article of secret composition should be admitted, no article which is sold under a proprietary name should be admitted under such a name if a substance of identical composition can be obtained under a nonproprietary name, no mixture of two or more active substances should be admitted unless evidence is submitted that the mixture presents therapeutic advantages over the simple substances, no proprietary article will be admitted before it has been accepted by the Council on Pharmacy and Chemistry of the American Medical Association for inclusion in New and Nonofficial Remedies, the oral should be given preference to the parenteral administration of drugs whenever possible.

Active cooperation is needed by all professions if a hospital is to maintain a progressive pharmacy. The physician should not prescribe any product unless he knows the truth about it at first hand or through an unbiased source, until he knows what the remedy contains or what it may reasonably be expected to do. The pharmacist has a store of information which is available for the asking, a closer acquaintance between him and the members of the attending staff will be of mutual benefit. The pharmacist in turn should be ready to offer up-to-the-minute information on problems within his purview and should not hesitate to advance his views in the interest of the hospital and patient.

The hospital pharmacy and the advisory pharmacy committee can be of added value by providing a list of materials which are scarce because of war and a list of substitutes which are satisfactory both clinically and economically. By maintaining a reference library on laws pertaining to the control of drugs, problems related to the prescribing of agents restricted to a physician's prescription can be obviated. As the hub of hospital materia medica, the pharmacy can serve as a fulcrum for many regular therapeutic conferences.

Obviously the hospital pharmacy is more than a place for the dispensing of drugs. In a sense it is a mirror which reflects the practice of that particular hospital and as such it should be the interest of all hospital departments. If this interest is not made evident, the pharmacy cannot be expected to function as it should, it will be no more than a tap to be turned on and off at will when a pill or powder is needed.

535 North Dearborn Street

Diabetes Mellitus in the Aged—It is estimated that there are nearly seven hundred thousand diabetics in the United States. Ninth most frequent cause of death, diabetes has a death rate of 238 per hundred thousand. Of those suffering this malady the majority exceeds 60 years, but while mortality is greatest in the seventh decade (288 for men, 328 for women) the onset is most common between 50 and 60 years (242, 303). The incidence rises steadily from 0.38 per cent below 14 years to 6.56 per cent at 45-54 years, 14.25 per cent the following ten years, and reaches 18.39 per cent after 65 years, with women prevailing slightly in the higher age groups—Mueller-Deham, Albert, and Rabson, *S. Milton Internal Medicine in Old Age*, Baltimore, Williams & Wilkins Company, 1942.

Clinical Notes, Suggestions and New Instruments

OLD STAB WOUNDS OF THE SPINAL CORD WITH SUBSEQUENT WIDESPREAD PIGMENTATION OF THE SPINAL CORD AND BASE OF THE BRAIN

W. A. JONES, M.D., LOS ANGELES

While stab wounds of the spinal cord are relatively rare lesions, retention of the foreign body in the spinal canal over a period of years is even more rare. The following is such a case.

REPORT OF CASE

A stab wound of the spinal canal at the age of 25 was followed by the first signs of paraplegia at the age of 43. A rusty knife blade was removed at the age of 45. Autopsy four months later revealed diffuse staining of the leptomeninges and surface of the cord with iron.

J. J. D., a Negro aged 45, was first seen on Dec. 14, 1938. He was examined because of paraplegia, which had been increasing for the past two years. At the age of 25 he was stabbed in the mid dorsal region with a knife. No immediate spinal cord symptoms appeared and no physician was consulted.

Fig. 1—Rusty knife blade removed at operation. This had lain in spinal canal for twenty-one years.

At the time subsequently he joined the army and served with the American Expeditionary Forces in France. He was discharged without disability on March 18, 1919.

Following this he worked as a janitor and did odd jobs. In 1936, eighteen years after the injury, he

first noticed difficulty in walking. During the next two years this weakness in his legs increased and by March 1938 he had become paraplegic and incontinent.

On examination, Dec. 19, 1938, he was found to have advanced spastic paraplegia. He was unable to walk. The left leg seemed weaker than the right. Sensory examination revealed retention of all sensory modalities and no definite level of sensory change could be made out. The abdominal and epigastric reflexes were very sluggish on each side. Cremasteric reflexes were lost. The deep reflexes of the upper extremities were increased with a bilaterally positive Hoffmann sign, greater on the right side. The knee jerks were very lively and about equal. The Achilles tendon jerks could not be obtained because of great spasticity. The Babinski, Rossolimo, Chaddock, Oppenheim, Gordon and Schaffer signs were all bilaterally positive. He also had bilateral ankle clonus. He had lost all control of the bladder and rectum.

Spinal fluid examination revealed a clear, colorless fluid under 80 mm of water pressure. The Queckenstedt test showed no block, the cell count was 9, globulin was normal, the Lange colloidal gold test was 0000000000 and the Wassermann reaction was negative. His blood Wassermann reaction also was negative. Roentgenograms of the spine revealed a fragment of an old knife blade which had penetrated the canal between the spinous process of the ninth and tenth dorsal vertebrae (fig. 2). The blade occupied a diagonal position with the point downward. This is contrary to the situation which obtains in most stab wounds of the cord, in which the knife blade usually points upward.

From the Department of Neurosurgery, Veterans Administration Facility.

Published with permission of the medical director, who assumes no responsibility for the opinions expressed.

On Jan 3, 1939, a laminectomy was performed and the knife blade removed. It was found on the right side of the spinal canal, its point being buried in the body of the tenth dorsal vertebra. While the blade had entirely transversed the

canal, it had not entered the spinal cord. Many arachnoidal adhesions were present and there was deep pigmentation of both the cord and surrounding tissues. This pigmentation was reddish brown and appeared to be due to iron pigment. The knife blade measured 7.5 cm in length and was very rusty (fig 1).

Following removal of the foreign body, the patient's condition did not improve. He remained paraplegic and incontinent and died four months later as the result of general debility.

At autopsy, April 19, the spinal cord was removed in toto. It was decidedly atrophied below the level of the eighth dorsal vertebra. The entire cord was stained uniformly brown throughout its length. The roots of the cauda equina were not stained but many of the higher spinal roots were brown. There were many arachnoid adhesions throughout the entire length of the cord. The base of the brain was also stained brown. This pigmentation extended as far forward as the chiasmal system (fig 3).

At the site of the injury, small fragments of iron rust were found embedded in the tissues. These were especially prevalent near the point of the knife blade where it had been

Fig 2—Lateral view of the spine showing indriven knife blade. The blade occupies a diagonal direction with the point directed downward. The point is embedded in the body of the tenth dorsal vertebra. Extensive corrosion of the blade is evident.

Fig 4—Section of the spinal cord at the level of the injury. Wide spread impregnation of the outer structures of the cord by particles of iron pigment is seen. Widespread gliosis is present.

Fig 3—Cross appearance of the base of the brain. Extensive pigmentation of the cerebellum and brain stem is seen. The pigmentation extends to the under and inner surface of the temporal lobes and to a lesser extent to the under surface of the frontal lobe.

embedded in the subdural space. The knife had not entered the cord but from this level downward the cord was definitely atrophied. Microscopic examination of the cord at the level of the injury revealed extensive infiltration of this structure with small particles of iron stained debris (fig 4). These particles were surrounded by areas of gliosis which were undoubtedly caused by the irritative action of the foreign bodies. The major ascending and descending tracts in the cord did not show degeneration but there was rather widespread glial proliferation throughout the section.

COMMENT

In 1932 Antonelli¹ reported a case of spastic paraplegia which developed thirty six years after a knife wound of the spinal cord. His case closely parallels mine. His patient was stabbed in the back at the age of 16 and the knife blade was

1. Antonelli, Giovanni. Spastic Paraplegia Developing Thirty Six Years After the Immediate Effects of a Knife Wound of the Dorsal Spinal Cord with Permanent Fixation of Fragment of Knife Blade. *Policlinico (ex med)* 39: 467 (Sept.) 1932, printed before *Cl. clinico Umberto I VII* Indigione, Rome June 5, 1932.

removed at the age of 52. Around the blade was found a collection of blackish semifluid and the surrounding tissues were deeply stained with iron. The blade had not entered the spinal cord. His paraplegia, which had been developing two years before his operation, did not improve following removal of the blade. It should be stated that he was given four treatments of neosarsphenamine for supposed syphilis before the development of paraplegia, and the question arises whether he may have had an arsenical myelitis. It seems more probable that this patient also had extensive gliosis of the spinal cord as a secondary reaction to iron pigment.

Special Article

NOTES ON PUERPERAL FEVER, 1843-1943

COMMEMORATING THE CENTENARY OF HOLMES'S
ESSAY "ON THE CONTAGIOUSNESS OF
PUERPERAL FEVER"

EDWIN F. DAILY, M.D.

Director, Division of Health Services, Children's Bureau,
U. S. Department of Labor
WASHINGTON, D. C.

One hundred years ago a 33 year old American physician Oliver Wendell Holmes convincingly described for the first time in this country the contagiousness of puerperal infection. His evidence, painstakingly pieced together from reports published both in Europe and in the United States and from his own observations in Massachusetts was presented with an eloquence which even he never surpassed in his extensive writing in later years.

The disease known as puerperal fever is so far contagious as to be frequently carried from patient to patient by physicians and nurses.

It would seem incredible that any should be found too prejudiced or indolent to accept the solemn truth knelled into their ears by the funeral bells from both sides of the ocean—the plain conclusion that the physician and the disease entered, hand in hand, into the chamber of the unsuspecting patient.

This long catalogue of melancholy histories assumes a still darker aspect when we remember how kindly nature deals with the parturient female, when she is not immersed in the virulent atmosphere of an impure living-in hospital, or poisoned in her chamber by the unsuspected breath of contagion.

The woman about to become a mother, or with her newborn infant on her bosom should be the object of trembling care and sympathy wherever she bears her tender burden or stretches her aching limbs. God forbid that any member of the profession to which she trusts her life, doubly precious at that eventful period, should hazard it negligently, unadvisedly, or selfishly.^{1,2}

Fifty years later Holmes wrote to a friend:

I do know that others had cried out with all their might against the terrible evil before I did, and I gave them full credit for it.

But I think I shrieked my warning louder and longer than any of them and I am pleased to remember that I took my ground on the existing evidence before the little army of microbes was marched up to support my position.³

The extent of medical knowledge and the methods of treatment in this field prior to Holmes's contribution may be judged somewhat by passages from Mackintosh's book on puerperal fever, published in 1822.

It is really curious to look into the medical world for we shall find one celebrated man attributing all marked changes in the human body to the motion of the blood, another solely to nervous irritation, a third to inflammation of the mucous membrane of the intestines, while others ascribe all diseases to the liver, the spine, or the stomach exclusively, and the practice of each of these individuals is shaped according to his pathological opinions. We need not, therefore, feel surprised when we discover the practice of medicine to be so corrupted and empirical. One will be found to direct his whole attention to the abstraction of blood, another, to placebos and the whole tribe of nervous medicines, or to ptisans, others to purgatives, mercury, applications to the course of the spinal marrow, or tonics. If this be a true picture of the profession at large, we shall not be surprised that genuine accoucheurs (who are neither reckoned to be so wise nor so frank) should have been led to adopt an absurd pathology, and pursue, at all hazards, an uncertain treatment, in some of the diseases they are called upon to attend.⁴

It was generally believed early in the nineteenth century that puerperal fever was caused by atmospheric conditions, the diet or the emotions. The customary treatment included the withdrawal of 24 to 40 ounces of blood at the first bleeding and further bloodletting or application of leeches as seemed desirable.

Many of Holmes's contemporaries in the medical profession remained wholly unconvinced by his reasoning. Some years later Dr. Meigs, professor of midwifery and the diseases of women and children at Jefferson Medical College, Philadelphia wrote concerning puerperal fever:

The contagious nature of puerperal fever though asserted by so many of the brethren entitled to my respect for their learning and judgment and humanity, I cannot for a moment admit.⁵

In Dewees's textbook which was widely used in this country at that time, the following appeared in 1847:

Had not the belief that puerperal fever was a contagious disease, and had not this belief a great effect upon the minds of females who are pregnant, we should not have touched upon this subject believing as we do that the opinion is altogether without foundation at least in this country.⁶

After the storm of controversy following his original paper, Holmes, in republishing his essay in 1855, ended his introduction with these words, forged at white heat:

There is no quarrel here between men, but there is deadly incompatibility and exterminating warfare between doctrines.

Let the men who mold opinions look to it, if there is any voluntary blindness, any interested oversight any culpable negligence even, in such a matter, and the facts shall reach the public ear, the pestilence carrier of the lying-in chamber must look to God for pardon, for man will never forgive him.⁷

At the time Holmes first published his essay in America, 829 of the 5,139 women delivered in the maternity hospital in Vienna during the period 1841-1843 died, a death rate of 16 per cent. In 1847, Semmelweis, a

2 Cullingworth, Charles J. Oliver Wendell Holmes and the Contagiousness of Puerperal Fever. London: Henry J. Glisher, 1906. pp. 24-25.

recent medical graduate working in this hospital, declared that the cause of puerperal fever was conveyed by the examining finger of the doctor or midwife, by instruments, by sponges or, more rarely, by air. He instituted the practice of washing the hands with chlorinated lime water, and the mortality in the clinic within a year fell to 3 per cent and a year later to 1.3 per cent, not because of improved therapeutic measures, for there were none, but because of effective prophylaxis. Not until 1861 did Semmelweis publish his great treatise on the subject.⁸

Le Fort, quoted by J. M. Duncan, reported in 1866 that the maternal mortality in French hospitals was 1 in 29, with some hospitals losing 1 out of every 7 maternity patients. Duncan, after an exhaustive study of the statistics of private practice in hospitals in Europe, concluded in 1871 that

not fewer than 1 in every 120 women delivered at or near the full time died within the four weeks of childbed. In a well managed hospital they die at the rate of 1 in 100, all the country over, the mortality is probably not much less, in the best private practice it appears to be greater.

Between one third and one half of these deaths were attributed to puerperal fever. Although this book was written almost thirty years after Holmes's famous essay, Duncan still believed that the term "preventable," as used in connection with puerperal fever, "is sufficient proof of the thoroughly unpractical or sensational character of the speculations of any writer who uses it as implying that we have the means of preventing its appearance." And he went on to say "It is, in truth, as little preventable as any disease in the nosology, or any crime in the statute book. It is, possibly preventable, but it has certainly never been prevented." Curiously enough, in later chapters of the same book Duncan, in making recommendations concerning the construction of maternity hospitals, urged that women attacked by puerperal fever should be placed in an infirmary which had no direct communication with the maternity hospital and even that the infirmary linen should be washed "in its own wash house." He also advised that maternity hospitals should be arranged in such a manner as to admit not more than 800 to 1,000 women annually.⁹

Not until 1867 did Lister give to the world his essay "On the Antiseptic Principle in the Practice of Surgery,"¹⁰ and in 1879 Pasteur published his observations that the streptococci (chapelets en grains) were the organisms causing puerperal fever,¹¹ thus scientifically establishing the basis for the prevention of puerperal infection.

The ponderous wheels of progress turned slowly. Hospitals began to be constructed and maintained with proper safeguards for the protection of maternity patients. The principles of aseptic technique became more generally understood and practiced by physicians. The practice of training and using skilled nurses was slowly spreading over the world.

Cullingworth² reported in 1905 to the British Medical Association

During the fifty-seven years 1847 to 1903 for which statistics for England and Wales are available, there were registered no fewer than 93,243 mothers as having died of puerperal septicemia, and the enormous sacrifice that these figures represent has been going on steadily all the time and shows no signs of diminution. If there be any change at all, it is in the direction of increase.

and let it be remembered that the returns of the Registrar-General take no account of the vast array of nonfatal cases, with their train of suffering and often of permanent ill health, or of the many fatal cases that for various reasons have been attributed on the death certificate to some other than the true cause. Puerperal fever continues to prevail as though Pasteur and Lister had never lived.

However, the data presented by Arnold Lea in 1910 show the mortality from puerperal infection (excluding infected abortions) in England and Wales averaging 1 such death for every 400 births during the twenty years preceding 1903 and a decrease to 1 such death for every 600 births during the four years 1903 to 1907. Statistics from some sections of the Continent suggested a decrease of 25 to 30 per cent in the maternal mortality from infection during the last twenty years of the nineteenth century.¹² The seeds planted by Holmes and Semmelweis were beginning to bear fruit.

Comparable statistics were not compiled in the United States in the nineteenth century, but we do know that in the state of New York in 1908 one woman died of puerperal infection for every 400 live births.¹³ This same mortality rate of 1 death from puerperal infection for every 400 live births was reported by the Bureau of the Census for the United States birth registration area from 1915 through 1935. Approximately 40 per cent of these deaths followed abortions. From 1935 through 1941 the United States mortality rate from puerperal infection decreased 50 per cent,¹⁴ most of the decrease occurring before the sulfonamides were in general use.

By 1941 in England and Wales only 1 out of 2,000¹⁵ and in the United States 1 out of 1,300 mothers died after delivery from puerperal infection (abortion deaths excluded). Only 1,943 deaths from puerperal infection following delivery were reported in the United States in 1941.¹⁶ Most, if not all, of these were, of course preventable. Many physicians now practicing obstetrics in the United States will probably not encounter the tragedy of a maternal death from infection in a lifetime of service. What a far cry from the experience of the Boston physician² who wrote Dr. Holmes that he had lost 5 patients from puerperal fever between May 7 and June 17, 1842.

The advances in the science of obstetrics initiated by Holmes and the great men who followed him have in a century practically swept from the civilized world one of the most devastating diseases of mankind.

It is hoped that these fragmentary notes from this period of medical history may serve to remind us again of the courage and wisdom of one of America's greatest men of medicine.

Council on Pharmacy and Chemistry

REPORTS OF THE COUNCIL

THE COUNCIL HAS AUTHORIZED PUBLICATION OF THE FOLLOWING
STATEMENT AUSTIN E SMITH, M D, Secretary

STATUS OF THE ORAL USE OF THE SODIUM SALTS OF THE SULFONAMIDES

The oral use of the sodium salts of the sulfonamides has been the subject of discussion and dispute and innumerable inquiries. Economic and therapeutic factors have been concerned in the origin of the inquiries and, while opinion has been divided in some instances, it appears that some degree of skepticism has greeted the general adoption of the procedure. Accordingly, when one manufacturer submitted its brand of sulfathiazole sodium for oral use a review of the existing evidence on this subject was made.

Some of the information supplied by the firm includes studies on monkeys and human individuals which had been carried out in its laboratories and elsewhere. Some of the latter data have been published or are in the process of publication.

Of 8 monkeys which received 1 Gm of sulfathiazole or sulfathiazole sodium, those receiving sulfathiazole experience a mean blood concentration (free sulfonamide) of 275 mg per hundred cubic centimeters at the end of one hour, 11 mg at the end of three hours, 1235 mg in five hours and 11 mg in eight hours, while those monkeys receiving 1 Gm of sulfathiazole sodium obtained a mean blood concentration of 125 mg in one hour, 1812 mg in three hours, 1375 mg in five hours and 8 mg in eight hours. Unfortunately, an estimate for the second hour was not reported to the Council.

Comparative studies were reported on 3 normal men who were given a single dose of 4 Gm of sulfathiazole two and one-half hours after a light breakfast, and five days later 4 Gm of sulfathiazole sodium. At intervals of one, three and seven hours the blood concentration of free sulfonamide after sulfathiazole administration (for the three subjects) was 24, 13, 21, 40, 46, 44, and 38, 45, 23, and after sulfathiazole sodium 73, 46, 47, 58, 69, 73, and 33, 47, 38. The firm stated that the patients "tolerated sulfathiazole without symptoms," but "all had slight abdominal discomfort (characterized by gas) from one and one-half to five hours after medication with sulfathiazole sodium, 1 of the 3 men was slightly nauseated."

In commenting on a report by Carroll, Kappel and Allen,¹ the firm averred "The average greatest blood concentration of the drug occurred between two and three hours after ingestion, one hour earlier than the maximum concentration which occurred after sulfathiazole administration." Reference to another paper, by Wheeler and Plummer,² revealed an apparent increase in the blood level following single 4 Gm doses of sodium sulfadiazine over that for sulfadiazine, but the difference was not extreme between 3 and 4 mg for free sulfadiazine at the end of two hours, as compared to between 6 and 7 mg for sulfadiazine sodium and 5 to 6 mg at the end of four hours for sulfadiazine as compared to 7 to 8 mg for sulfadiazine sodium. In all reported instances, as far as could be determined from the firm's brief, only one dose appears to have been given for blood estimations.

Other reports on blood estimations, elimination and therapeutic actions were given. In the case of the latter, however, controls with the free sulfonamide seemed to be in the minority. It is difficult to estimate accurately the possible efficacy of a sodium salt of a compound such as a sulfonamide unless concurrent tests on controls with the free sulfonamide are undertaken and reported, the degree of uncertainty in clinical interpretation and the margin of possible error in compiling evaluations are very real factors influencing this estimation. Tolerance of the sodium salts in oral therapy was reported as favorable or "better," but again the firm failed to submit details of controls.

In reviewing the subject of the oral use of sodium salts of the sulfonamides there are three questions to be answered: 1 Are the sodium salts of the sulfonamides more effective as therapeutic agents than the free sulfonamides? 2 Are the sulfonamides more rapidly and more completely absorbed when given orally in the form of the sodium salts? 3 Are they more readily tolerated?

With regard to the first question there is not enough evidence available at the present time to show that the sodium salts are more effective therapeutic agents in the treatment of infections than the free sulfonamides. Their effect would appear to be equal to that of free sulfonamide therapy, but this is not surprising since the sodium salt is converted into the free sulfonamide in the stomach when acid is present.

With respect to the second question, there seems to be no doubt that the sodium salts of sulfadiazine, and thus probably is true of sodium sulfathiazole as well, may be absorbed more rapidly and more completely than the free sulfonamides when it is given by mouth to the fasting subject or when it is given directly into the duodenum by duodenal tube. When it is given after a meal the absorption is delayed and less can be absorbed than when it is taken in the fasting state.

With regard to the third question, the only answer is that there is no evidence which is convincing that the sodium salts are more readily tolerated than the free sulfonamides.

In view of the fact that it is necessary to give the sodium salts directly into the duodenum or to a fasting subject in order to get more rapid absorption than when the free sulfonamides are given, there would seem to be no good reason for accepting the sodium salts for oral administration at the present time.

If it could be shown that the sodium salts were better tolerated and that the therapeutic results were better, then the Council might consider the sodium salts for oral administration.

After due consideration of the evidence presented by the manufacturer submitting sulfathiazole sodium for oral use and of that available from other sources, the Council decided that the work done to date is insufficient to justify recognition of the claimed therapeutic advantage, further, the Council has inadequate information with respect to proper dosage of the drug and, if the drug is absorbed much more rapidly, as is claimed, additional evidence with respect to safety seems necessary. The Council recognizes the value of decreasing the time necessary for clinical response following drug administration and will again give consideration to the subject when more conclusive evidence has been presented or made available. Until that time, if it is necessary to bring the blood levels up to the optimal figures immediately, the parenteral use of the sodium salts should be given preference.

NEW AND NONOFFICIAL REMEDIES

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED AS CONFORMING TO THE RULES OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO NEW AND NONOFFICIAL REMEDIES. A COPY OF THE RULES ON WHICH THE COUNCIL BASES ITS ACTION WILL BE SENT ON APPLICATION.

AUSTIN E SMITH, M D, Secretary

NIKETHAMIDE (See Supplement to New and Nonofficial Remedies, 1942, p 17)

SCHOOLS FOR MEDICAL RECORD LIBRARIANS	PAGE 1088

One person every 2.5 seconds is the rate at which patients entered hospitals in the United States during the year 1942. Nearly one tenth (9.5 per cent) of the entire population (1940 census) became a hospital bed patient. Surgical operations were at the rate of one to each 5.6 seconds and the hospital birth rate exceeded three live babies to the minute.

A total of 6,345 registered hospitals is represented in the following report on the Twenty-Second Annual Census of Hospitals by the American Medical Association. This is a decrease of 13 in the number of hospitals on the Register one year ago.

persistently followed up by letters, telegrams and long distance calls.

In the use of population figures in this article it was decided most reliable data would result from using the United States Census Bureau figures of 1940 rather than the Bureau's estimates for 1942.

There is some incompleteness, extent unknown, in figures on recently established federal hospitals due to withholding of information that might be of assistance to our country's enemies.

To the questions as to whether the hospital has a blood bank, a plasma bank and whether these were

SUMMARY OF HOSPITAL DATA

	Number	Beds	Bassinets	Patients Admitted in 1942
1 Registered hospitals and sanatoriums approved for internships, residencies and fellowships	1,070	544,489	32,349	6,002,666
2 Other registered hospitals, sanatoriums and related institutions	5,275	839,338	39,099	6,542,944
Total registered	6,345	1,383,827	71,448	12,545,610
Of the foregoing the American College of Surgeons approves	2,404	767,384	48,911	8,948,126

Found unsatisfactory on investigation (capacity 15,260)

Unclassified emergency stations, clinics, offices, cottages and so on with facilities for bed care (capacity unknown)

Hospitals and sanatoriums opened Registration pending

*As of Dec. 31, 1942

Number
539
2,698
62

The capacity of registered hospitals is 1,383,827 beds and 71,448 bassinets. There are 59,446 more beds and 5,285 more bassinets than one year ago. This growth in hospital facilities for the past year was the equivalent of a 163 bed hospital for every day in the year.

For thirty-one years prior to 1941 the average annual growth of hospital facilities was around 25,000 to 30,000 beds.

Grateful acknowledgment is made for the cooperation of officers of hospitals and others who, in spite of war conditions, have furnished the data which make possible the great amount of valuable information that is presented in this issue. Reports were received from over 99 per cent of the hospitals addressed.

The reports by and large were more complete and more accurate than in any previous year. The relatively few incomplete reports and tardy ones were

readily available outside if not in the hospital, 610 have blood banks, 1,741 have plasma banks, 546 have both while 2,457 have such facilities readily available but not in hospital.

The total number of patients admitted during the year was 12,545,610, an increase of 949,422, or 8.2 per cent, over the previous year.

The total of hospital patients operated on during the year was 5,607,879, or 44.7 per cent of all who were admitted for bed care.

The present report covers the calendar year for all the hospitals approved for internships and residencies and many others, but many of the hospitals that are registered but not approved reported for the year ended Sept. 30, 1942. The hope is entertained that the census may before long be placed on the basis of a uniform census period, preferably the calendar year.

The total patient days of hospital service for 1942 was 411,000,220, an increase over 1941 of 14,230,985. The number of patient days is obtained by multiplying the average daily census, 1,126,028, by 365.

There are 1,439 schools of nursing that are accredited by state boards of nurse examiners. Their total student

Percentage of Beds Occupied

	1940	1941	1942
According to Ownership or Control			
Federal	70.5	66.3	66.6
State	94.4	93.0	93.4
County	85.0	84.7	77.7
City	80.5	78.2	76.9
City county	65.5	73.7	70.5
Total governmental	89.8	80.2	84.5
Church	70.4	73.1	74.0
Nonprofit associations	70.8	72.7	74.5
Total nonprofit	70.6	73.2	74.7
Individual and partnership	52.0	57.7	56.1
Corporations (profit unrestricted)	62.5	64.5	65.3
Total proprietary	56.8	60.8	60.4
Total nongovernmental	68.5	71.4	72.7
According to Type of Service			
General	70.3	65.2	65.2
Nervous and mental	95.1	94.5	94.4
Tuberculosis	85.6	85.7	85.0
Maternity	62.6	65.3	70.7
Industrial	53.0	56.2	55.5
Eye, ear, nose and throat	54.4	55.5	51.9
Children	68.2	68.1	67.4
Orthopedic	76.5	77.1	75.4
Isolation	42.4	35.0	35.2
Convalescent and rest	77.7	82.7	82.1
Hospital departments of institutions	70.6	76.2	66.4
All other hospitals	79.9	85.6	81.1
Total all hospitals	83.7	82.1	81.4

The total number of all registered hospitals closed during the year was 122. An additional 51 discontinued their hospital services entirely or to the extent that they would no longer be classified as hospitals or related institutions. Eleven registered hospitals were removed from the list because of their admitted failure reasonably to comply with the Essentials of a Registered Hospital.

AMERICAN COLLEGE OF SURGEONS AND A M A UNITE ON ANNUAL CENSUS BLANK

For the third time the questionnaires used by the Council represent a combination of the annual census blank of the American Medical Association and the annual questionnaire of the American College of Surgeons. Cooperation of the College and the Council was effected to reduce work of filling out questionnaires in the office of hospitals. It also facilitates the gathering of essential data required by the two cooperating organizations for their use, and for the nation. Most of all, it reduces the confusion which exists when several organizations are working in the same field.

Each organization has its own distinctive separate requirements, inspections and approved lists. Approval of a given institution by one organization does not in any way affect the initiative and the responsibility of the other organization with regard to the approval of that institution. There is cooperation as to the joint questionnaire, correlation of inspection itineraries and mutual courtesy in the use of symbols to designate each other's approvals.

All general hospitals	14 days	12 days	13 days

The officials of the A M A and the College, and their office staffs, worked together to design a questionnaire that would elicit more information with fewer questions and achieve greater uniformity and simplification in the use of terms. All the hospitals that are fully approved as meeting the minimum standards of the American College of Surgeons are designated with a delta (Δ) in the list of registered hospitals published in a later section of this article.

enrollment reported is 98,166, a loss of 9 schools but a gain of 4,189 in enrollment.

Special attention of persons interested in growth of hospital facilities is directed to the year by year summaries in the footings of tables 1 and 2.

As to what classes or groups of hospitals are responsible for increases and decreases during the year, the total governmental hospitals showed an increase in number from 1,864 to 1,924.

GOVERNMENTAL HOSPITALS

Under the total governmental hospitals are included those operated by different arms of the federal government, by states, by counties, by cities and by cities and counties combined.

The total bed capacity of the governmental hospitals rose from 965,511 to 1,015,781 and of bassinets from 11,494 to 11,828. The patients admitted to governmental hospitals increased from 3,662,602 to 4,009,675, and the average census rose from 831,892 to 858,638.

The federal hospitals totaled 474 as compared with 428 a year ago, their total bed capacity being 220,938 as compared with 179,202 a year ago. Bassinets increased from 1,006 to 1,206. The number of patients reported as having been admitted rose from 1,268,112 to 1,675,722, and the average census was 147,094 as compared with 118,890 for the previous year. Continuing to examine the footings of table 1, it will be observed that very few changes—no striking increases or decreases—are found in any of the capacity or occupancy columns for hospitals operated by states, counties, cities or those run jointly by cities and counties. The increases and reductions in number of hospitals in each classification, it should be remembered, are net figures after taking into account hospitals that were closed during the year and the new hospitals opened.

NONGOVERNMENTAL HOSPITALS

In the field of nongovernmental institutions there are 4,421 hospitals—a reduction in number from 4,494 nongovernmental hospitals existing a year ago. Their bed capacity at present, however, is 368,046, a considerable increase over 358,870 reported last year. Their bassinets now number 59,620 as compared with 54,669 a year ago. The total patients admitted were 8,535,935, showing quite a large increase over their former figure, 7,933,586. The average census changed during the year from 255,147 to 267,390.

The nongovernmental hospitals fall readily into two general groups—the nonprofit organizations section B of table 1, composed of those that are church related, and other nonprofit associations, and section C of table 1, composed of hospitals that are owned by individuals or partnerships and those owned by corporations that are unrestricted as to profit. In the nonprofit group are 2,926 with a capacity of 316,291 and 51,416 bassinets to which were admitted 7,463,648 patients and which had an average census of 236,154. The nonprofit group, therefore, showed a strong increase, and the growth was shared in some part by the church related hospitals but to a much greater extent by the other nonprofit associations.

Church hospitals show a net loss from 993 to 977 but a considerable increase in the number of beds and bassinets. Their patients admitted increased from 2,961,594 to 3,211,162 and their average census from 90,195 to 94,521.

The other nonprofit associations increased in number from 1,917 to 1,949 and in capacity from 182,140 beds to 190,150 beds and in bassinets from 26,422 to 29,154. They admitted 4,252,486 as compared with 3,931,141 last year, and their average census was 141,633 as compared with 132,472 last year.

HOSPITALS ACCORDING TO TYPES OF SERVICE

The hospitals that have been registered nearly all fall easily into twelve classifications as to the type of service rendered. These together with the number of hospitals now in each classification are as follows: general 4,557, nervous and mental 586, tuberculosis 468, maternity 113, industrial 36, eye, ear, nose and throat 42, children's 43, orthopedic 79, isolation 52, convalescent and rest 139, institutional 194, all other types 36. Among all these classes as to types of service there was little change in number or capacity or the amount of service rendered during the past year, except in the general hospitals, and there we find a very great increase.

The number of general hospitals had a net increase of 39. Their capacity increased from 533,498 beds to 594,260, the bassinets from 61,732 to 67,115. The patients admitted reached the enormously large total of 11,634,288 as compared with 10,646,947 in the preceding year.

The trends in all the classifications as to type of service are shown in the footings of the various columns of table 2. The recapitulation by years covers each annual census of hospitals beginning with that of 1927.

PERCENTAGE OF BEDS OCCUPIED

The percentage of beds occupied is obtained by dividing the number of beds, not including bassinets into the average number of bed patients in the hospital, not including newborn infants and of course, not including outpatients. The percentage of beds occupied is presented in the accompanying table to assist the reader

in understanding the situation in 1942 and also in observing the trend for the past three years 1940, 1941 and 1942. The percentage of occupancy in all hospitals in those three years decreased steadily from 83.7 per cent to 81.4 per cent. Closer examination shows, however, that the nongovernmental hospitals increased in occupancy during the same period from 68.5 per cent to

72.7 per cent, the increase being found in all groups of nongovernmental hospitals, including church related, nonprofit associations and proprietary institutions.

It is in the field of governmental hospitals that the rate of occupancy shows a downward trend from 89.8 per cent in 1940 to 84.5 per cent in 1942. During that period federal hospital occupancy declined from 79.5 per cent to 66.6 per cent. State, county and city hospitals as groups each showed a decline. Persons who are looking for figures to guide them in regard to individual projects should not base their conclusions on figures that arise from group comparisons, such as are made

here, because a separate analysis for each individual project or situation is necessary.

Among the hospitals classified as to type of service it is noted that general hospitals as a group were 70.3 per cent occupied in 1940, 68.2 per cent in 1941 and the

of 1929. More than 97 per cent of the births reported in 1942 were in general hospitals, 85 per cent, or a total of 1,420,079, were in nongovernmental hospitals, and the remaining 15 per cent or 250,520 were in governmental hospitals.

same 68.2 per cent in 1942. The trend has been upward in the occupancy rate of maternity hospitals and downward in children's, orthopedic and isolation hospitals, and not very decisively upward or downward in the other classifications as to types of service.

BIRTHS IN HOSPITALS

The total births in hospitals for 1942 was 1,670,599. This represents an increase of 265,659 over the 1,404,940 in 1941. Figures reported for births by hospitals refer to the number of live babies born. The hospital births in 1942 were nearly two and one-half times those

The average number of babies accommodated per bassinet during the year 1942 was 23.3, compared with 21.2 for 1941, 19.6 for 1940 and 12.9 for 1929, showing increasing utilization, from year to year, of the existing supply of bassinets.

TOTAL LIVE BIRTHS IN COMPARISON WITH LIVE BIRTHS IN HOSPITALS FOR 1931, 1936 AND 1941

The remarkably rapid gains in the use of hospitals for childbirth has seemed to justify showing the number of all births in comparison with the numbers and percentages of births in hospitals for the years 1931, 1936

and 1941. The total number of births in each state and in all states is supplied by the United States Bureau of the Census, and births in hospitals by the American Medical Association Annual Census. Nineteen hundred and forty-one was the latest year for which the births in the country at large have been made available by the Bureau of the Census, as this article is being prepared.

The fact that the Bureau of the Census figures include births in all institutions reported as hospitals, whereas the A M A Annual Census covers only registered hospitals.

The United States Bureau of the Census found that 94.2 per cent of the live babies born in hospitals in 1941 were white and 5.8 per cent were of other races.

In 1941, 55.9 per cent of all the live births occurred in hospitals. In 1936 the rate was 38.8 per cent and in 1931 it was 33.6 per cent. Not only is this a rapidly increasing rate but the rate of increase in the five year period that ended in 1941 was enormously accelerated over that of the period that ended in 1936. The number of births in hospitals in 1941 as obtained by the Bureau of the Census was 1,537,719, or 132,779 more than were given in the A M A Census of Hospitals for that year. The difference is accounted for in part by the

The total live births reported by the Bureau of the Census for 1941 together with live births in hospitals for that year have enabled us to present a map for the ready comparison of states in relation to the use of hospitals in childbirth.

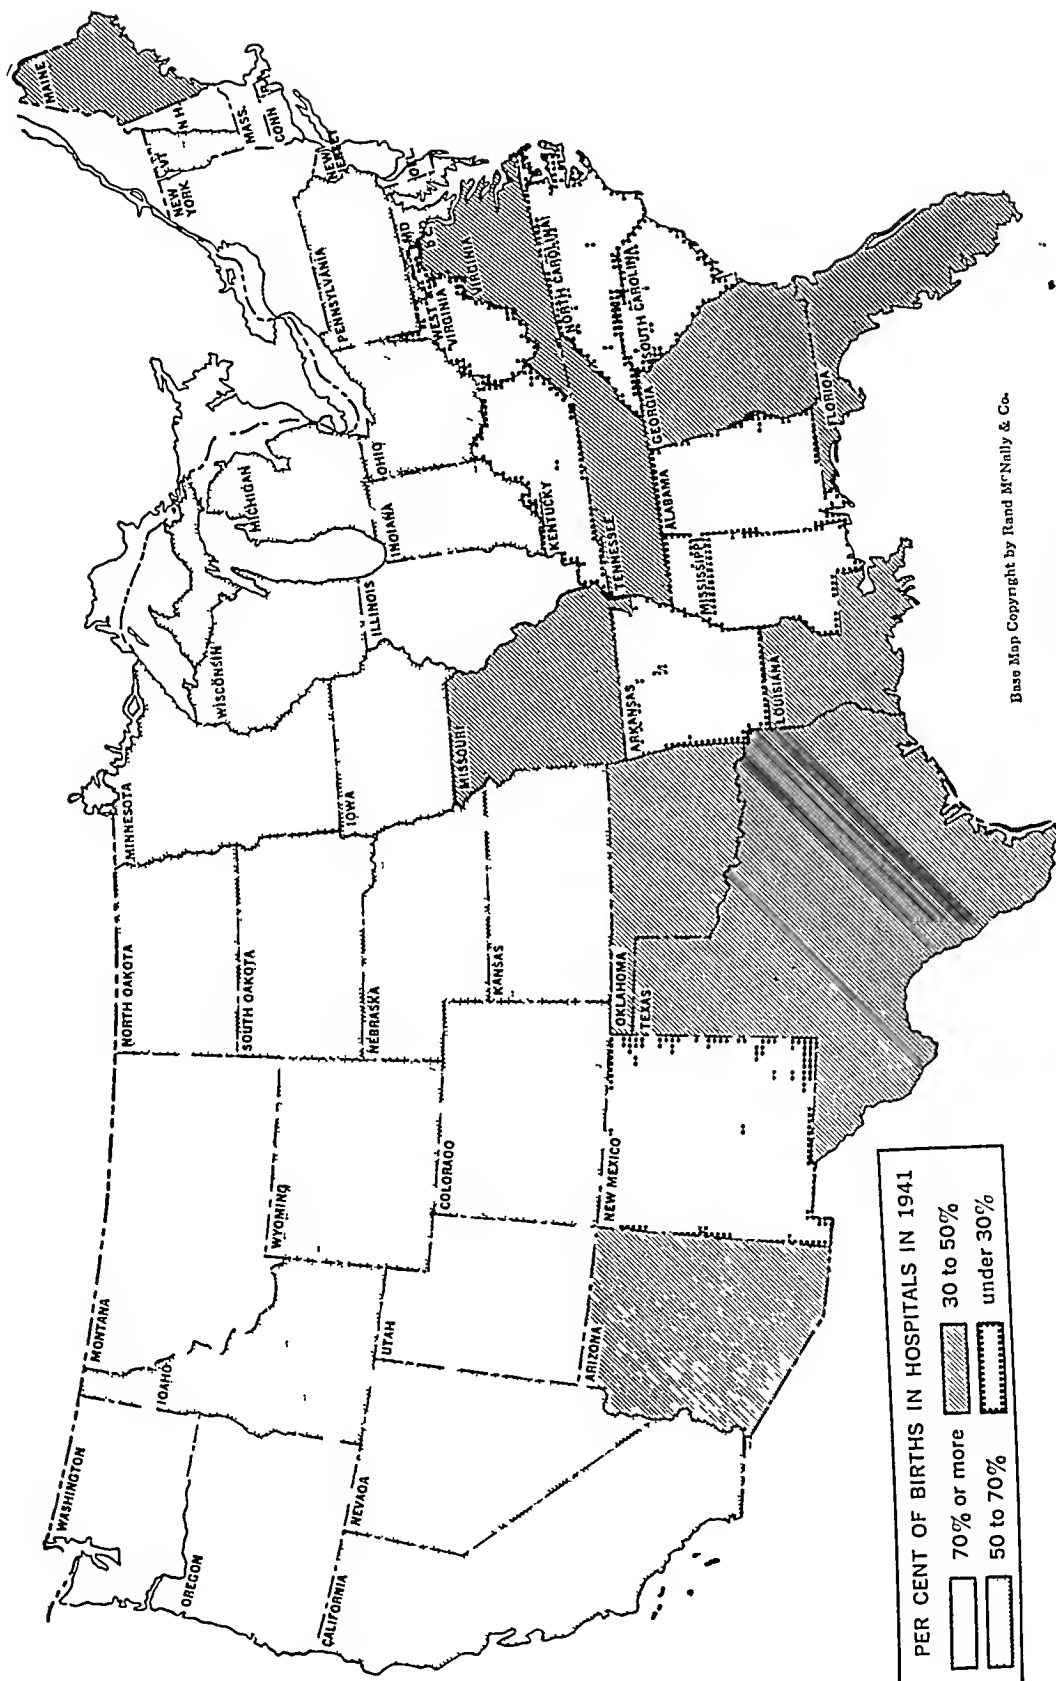

In the District of Columbia it will be observed that 93.8 per cent of the births in 1941 were in hospitals. The states that are in the high bracket and their percentages are as follows: New Jersey 92.2 per cent, Connecticut 89.4, New York 85.3, Massachusetts 82.1,

TABLE 2—HOSPITAL FACILITIES BY STATES AND BY TYPE OF SERVICE (Continued on next page)

equivalent to 9.5 per cent of the entire population according to the census of 1940. The incidence of hospitalization in terms of percentage of population hospitalized in each of the different states affords an especially interesting comparison. In the District of Columbia this amounts to 19.7 per cent of the population, a very high rate the result of conditions that are different from those of any state as a whole.

Among the states having a high percentage of population hospitalized were Nevada 15.4 per cent, Arizona 15.3, Wyoming 15.3, Washington 14.1, California 12.8 and Colorado 12.4. On the other hand, states having a low rate of hospitalization were Arkansas 5.4 per cent, Kentucky 6.0, Alabama 6.2, Mississippi 6.3, Tennessee 6.6 and Oklahoma 6.7.

In answer to the question as to how many patients were operated on during the year, we get a total of

5,607,879, or 44.7 per cent of the patients admitted. This is an increase of 406,229 over the patients operated on in 1941. The state turning in the highest percentage of patients receiving operations is New Hampshire with 54.0 per cent, which is closely followed by Pennsylvania with 53.7 and Rhode Island with 52.8. Thirty states and the District of Columbia had an operating rate between 40 and 50 per cent, fourteen states between 30 and 40, while the lowest record goes to Wyoming, which, as a state, reported 21.8 per cent.

HOSPITAL DEATHS AND NECROPSIES COMPARED WITH ADMISSIONS

The total number of deaths reported in all hospitals was 502,334 and the number of necropsies was 116,303, a necropsy rate of 23.2 per cent. In the preceding year the deaths had reached a total of 510,158 with 125,640 necropsies, a rate of 24.6. The present census shows a necropsy rate on the hospital deaths in the District of Columbia of 42.9 per cent. The states which achieved a comparatively high necropsy rate on hospital deaths

Hospital Deaths and Necropsies Compared with Admissions

	Deaths Excluding Stillborn	Number of Necropsies	Per cent of Necropsies	Patients Admitted Plus Live Births	Death Rate (Per Cent) of Admissions Plus Live Births

Wyoming	566	135	13.4	41,904	2.1
Totals (1942)	502,334	116,303	23.2	14,216,209	3.5
(1941)	510,158	125,640	24.6	13,091,125	3.9

during 1942 were Minnesota 33.8 per cent, Colorado 31.9, Missouri 31.5, Maryland 31.0, while California and Oregon tied at 30.2. An accompanying table gives statistics on hospital deaths and necropsies for all states.

The total number of patients admitted plus the number of live babies born in all states during the 1942 period was 14,216,209. The live births are added in this calculation because the number of deaths, 502,334,

included deaths of newborn infants. The over-all death rate for patients admitted to hospitals (plus live births) therefore was 3.5 per cent. This compares with the rate of 3.9 per cent for the preceding year. There

were fourteen states in which the hospital death rate was less than 3 per cent, and there were seven states in which it was over 4 per cent.

In view of the educational importance of necropsies this subject is discussed at greater length in that part of the article relating to internships, residencies and fellowships. In that section comparisons are made between the rates in all hospitals and the higher rates of necropsy performance in the hospitals that are approved specifically for educational purposes.

ADMINISTRATIVE PERSONNEL

The questionnaire used in the Annual Census asks for the name of superintendent or administrative head and the title of that person. The returns concerning all of the 6,345 registered hospitals give a total of 2,280 administrators or superintendents who hold the M.D. degree, 2,167 registered nurses and 1,898 other persons. The M.D. degree of each of the physicians was checked in the biographic files of the American Medical Association. The R.N. degrees were recorded as reported on the questionnaire. A physician owning a

hospital was not counted as the administrator or superintendent if the name of any other individual in charge was given. The number of physicians serving in this capacity has increased by 147 during the past year.

NURSING PERSONNEL

In order to ascertain the status of nursing personnel as of the date when the questionnaire was answered, the following questions were asked: "Number of graduate nurses employed on nursing service"

* Decrease

'Practical' nurses The answer gave a total of 120,114 graduate nurses, 22,161 practical nurses, 94,133 attendants and 25,857 orderlies. The question is limited to those employed on nursing service and does not include student nurses or nurses employed as anesthetists, technicians, instructors, superintendents or other non-nursing duties. With the rarest exceptions those reported as graduate nurses have the R.N. degree from their state board of nurse examiners. The increase in graduate nurses employed at nursing during the year is 7,272 and the increase in practical nurses is 4,829. The number of attendants decreased by 869 and the number of orderlies increased by 1,020.

SCHOOLS OF NURSING

The number of schools of nursing that have the approval of their respective state boards of nurse examiners is 1,439 as compared with 1,448 one year ago. The state board of nurse examiners, which usually has its office in the capitol building of the state, is the authority for the number of state accredited schools of nursing. The hospital which maintains the accredited school of nursing is the authority for the number of students enrolled as of date when questionnaire was

filled out. The total number of students enrolled in the accredited schools of nursing was 98,166 as compared with 93,977 one year ago. For more than a decade the number of accredited schools of nursing has been sharply reduced, while the number of students enrolled has constantly increased.

TECHNICAL PERSONNEL IN HOSPITALS

To keep pace with developments in the art and science of medicine it has become possible—and necessary—for physicians working in hospitals to use trained persons to assist them in many technical procedures connected with the care of patients. These are in addition to nurses. Some of the technical personnel,

figures on which are presented in an accompanying table, see and handle the patient. Others may not come in contact with the patient. All are essential for administering to the patient's comfort and care and saving the doctor's time.

Some statistics on technical personnel were presented in *THE JOURNAL*, March 27, 1937 and March 28, 1942. Statistics are now available showing the status of technical personnel in hospitals for the year 1942, which reveal a large and varied use of trained assistants and the augmented use of them under war conditions. The number of each of the twelve types of assistant in each state is shown, including those employed on full time and those on part time. The hospitals reported 3,274 nurse anesthetists on full time and 972 on part time, 10,961 laboratory technicians on full time and 1,835 on part time and 6,303 x-ray technicians on full time and 1,604 on part time. The dietitians number, full time and part time respectively, 6,077 and 557, physical therapists 2,643 and 772, pharmacists 2,698 and 533, medical stenographers 6,875 and 1,048, occupational therapists 1,727 and 283, dental hygienists 1,031 and 572. In social service there are 3,618 workers on a salary and 2,033 are voluntary. In all these groups there is noted a considerable increase over the previous year except in the case of occupational therapists and part time dental hygienists in which slight decreases are noted.

Medical record librarians number 3,426 full time as compared with 3,035 a year ago and 1,035 part time as compared with 897. Other librarians have increased from 678 to 780 full time and 464 to 524 part time.

A special report on the work of the Council on Medical Education and Hospitals with reference to laboratory technicians, physical therapy technicians and occupational therapists, and lists of approved schools for their training, will be found in later pages of this issue. There is also an announcement regarding the work assigned to the Council by the House of Delegates at the 1942 meeting relative to the formation of standards and the preparation of lists of schools for medical record librarians.

REGISTRATION AND APPROVAL

It is well to distinguish between registration and approval of hospitals. Registration means the inclusion of a hospital in the list maintained by the Council on Medical Education and Hospitals and published in the Hospital Number of *THE JOURNAL* and in the American Medical Directory. The Essentials of a Registered Hospital are used as a guide in considering hospitals for registration and are employed in such a way as to raise the standards of hospitals and to point the way to better service.

Approval means specific endorsement of hospitals for educational purposes, the fitness for which is determined by observation, inspection and comparison with definite requirements for the training of interns and residents.

Registration is a basic recognition extended to the hospitals and related institutions concerning which the Council has no evidence of irregular or unsafe practices. Approval is designation of certain registered institutions by the Council for internships, residencies and fellowships.

The term approved as used by the College of Surgeons may be applied to those registered hospitals that meet the minimum standards of the College.

The registered hospitals are printed in a list on later pages of this issue. Approval of the Council for internship is shown by a star (*), approval of residencies by a plus (+) sign. Approval by the American College of Surgeons is shown by the delta (Δ) and approval by the state board of nurse examiners by the diamond (◇).

HOSPITAL FACILITIES NOT IN THE REGISTER

At all times there are some hospitals that are in formative stages or that lack further development and are not ready for registration.

There are other facilities that are omitted from the list of registered hospitals, such as follow methods and practices that are generally recognized as unsatisfactory or dangerous and that therefore need complete change of policy before being recommended to the public. Their number at the present time is 539. Their capacity, according to the latest available information, is 15,260, or less than two thirds of 1 per cent of the facilities furnished by the hospitals recognized in the Register. Each year a number of such institutions close.

Summary of Growth of Hospitals 1909 to 1942

Year	Federal Hospitals		State Hospitals		All Other Hospitals		Total	
	Number	Capacity	Number	Capacity	Number	Capacity	Number	Capacity
1909	71	8,427	232	189,049	4,056	233,119	4,459	421,065

1937	316	83,303	526	483,994	5,404	501,792	6,746	1,075,139
1938	323	84,234	524	503,306	5,342	509,101	6,189	1,096,721
1939	329	97,901	512	506,913	5,277	517,604	6,128	1,121,548
1938	310	92,248	523	511,210	5,313	527,003	6,166	1,161,300
1939	329	96,335	523	500,000	5,374	530,113	6,206	1,190,076
1940	310	108,928	521	572,079	5,474	544,735	6,291	1,226,243
1941	424	179,262	530	600,370	5,409	544,530	6,315	1,224,581
1942	471	220,935	530	600,437	5,341	556,452	6,342	1,333,827

their doors and a few pass into competent hands or make improvements to qualify for registration.

Another class of facilities not appearing in the Register includes emergency stations, clinics, offices and so on, with some facilities for at least occasional bed care, attached or available. They are recognized as ethical and valuable auxiliary facilities to the hospital system. Most of these unclassified facilities have 3 to 10 beds each, which are used as occasion demands. Some of them are sickrooms attached to small custodial institutions. The bed capacity of these institutions, usually spoken of as unclassified, is too variable to be positively enumerated. Hospitals that are not named in the registered list may apply at any time and be given consideration in accordance with the Essentials of a Registered Hospital.

The Essentials of a Registered Hospital, adopted by the House of Delegates of the American Medical Association, suggest minimum standards for hospital service in the best interests of the patient. The Essentials are distributed in pamphlet form on application and have been a force of appreciable educational value to hospitals.

Opportunity always is open for unregistered hospitals to make application through the Council on Medical Education and Hospitals.

INTERNSHIPS, RESIDENCIES AND FELLOWSHIPS

(As of March 1, 1943)

NUMBER OF INTERNSHIPS

In the present discussion of internships, residencies and fellowships the federal hospitals approved by the Council are omitted for reasons of military security. Aside from these institutions there are now 702 hospitals approved for intern training. They can accommodate 7,959 interns but have only 5,567 on duty at the present time, indicating a shortage of 2,392. Since the number of admissions in the approved internship hospitals was 5,121,911 in 1942 and the average daily census 171,636, it is apparent that the general over all ratio of interns to patients is now 1 to 920 annual admissions, or 1 to every 31 patients currently under treatment. It should be noted however, that the hospitals holding internship approval have an additional house staff of 3,207 resident physicians, including 154

TABLE A—Number of Internships 1914-1943

	Number of Hospitals	Available Internships	Medical Graduates (United States)
1914	505	2,067	3,594
1916	519	2,709	4,018
1920	461	2,969	4,017
1921	482	2,962	2,156
1922	492	3,063	2,220
1923	500	3,119	3,120
1924	518	3,269	3,662
1925	623	3,422	3,974
1926	631	4,727	3,962
1927	673	4,122	4,033
1928	611	6,109	4,262
1929	671	5,409	4,446
1930	631	5,331	4,363
1931	674	6,131	4,755
1932	696	6,961	4,926
1933	631	6,201	4,895
1934	616	6,201	5,033
1935	697	6,419	5,101
1936	700	6,739	5,183
1937	712	7,167	6,277
1938	729	7,334	5,191
1939	721	7,833	6,039
1940	722	7,993	5,977
1941	733	8,189	6,276
1942	722	8,181	5,163
1943	702*	7,959	5,567†

* Does not include federal hospitals approved for intern training.

† Estimated number for the entire calendar year under accelerated program of medical education.

general residents whose service usually corresponds to a second year internship. Considering the entire house staff of 8,773, the ratios become 1 to 583 admissions, or 1 to approximately every 20 patients now under hospital care. The number of outpatient visits in these hospitals was 20,257,848 last year.

Table A, illustrating the increase of internships from 1914 to 1943, shows the number of hospitals and available internships in relation to the annual output of medical graduates in the approved medical schools of the United States. In this connection it is of interest to note that when the first list of approved hospitals was published in 1914 only 70 per cent of the medical graduates were applying for internship appointment. In recent years 99 per cent have taken at least one year of hospital training after graduation, even though an internship is not required for licensure in twenty-six states.

The number of hospitals approved for intern training in each state is shown in table B.

SHORTAGE OF INTERNS

For several years the number of available internships has exceeded the annual number of medical graduates, but many of the surplus appointments have usually been filled by second year interns and graduates of

* Does not include federal hospitals approved for intern training.

medical schools outside the United States. Vacancies have been increasing, however, and are now becoming more apparent since the use of second year interns has necessarily been curtailed. In 1939 only 317 vacancies were reported but these increased to 344 in 1940, 615 in 1941 and 1,128 by January 1942. Currently the number of unfilled positions in hospitals approved for intern training is 2,392, as indicated by the report of 7,959 internships available and 5,567 interns employed (table B).

In the face of this shortage it would seem particularly important that all hospitals cooperate in an effort to maintain an equitable distribution of interns by limiting their appointments to actual minimum needs. As a general rule the ratio of house officers to patients should not exceed 1 intern to 600 annual admissions. Economy in the use of interns is important not only from a numerical point of view but also in relation to individual duties and assignments. Thus to conserve the interns' time for essential hospital and educational needs the routine procedures which do not contribute materially to the training course should be shifted to nursing and technical personnel whenever possible. Obviously when an intern group has been diminished it may likewise become necessary for the members of the attending staff to take over many of the functions ordinarily assigned to house officers. Under present conditions it is increasingly important that the educational character of the internship be preserved. The employment of interns, therefore, should not be viewed primarily as a means of supplying personnel in relation to institutional service.

The Council has recently declared that hospitals approved for internships and residencies may accept graduates of Latin American schools as interns or residents, the responsibility for the evaluation of credentials of each applicant to rest with the hospital involved. Similarly, graduates of European medical schools may be appointed if their qualifications are found to be satisfactory. Again the responsibility for evaluating credentials must necessarily rest with individual hospitals, since foreign medical colleges have not been investigated and classified by the American Medical Association as in the case of the United States and Canadian schools. The shortage of interns might also be relieved to some extent by the employment of second year interns and general residents when such applicants are available. In this connection it should be noted that all hospitals approved for interns are likewise accredited for general or mixed residency training.

LENGTH OF INTERNSHIPS

There has been considerable discussion regarding the length of internship during the present accelerated program of medical education. However, it has not become necessary to reduce the intern training program below one year even though medical students are now graduating at intervals of nine months. Both the Council on Medical Education and Hospitals and the Association of American Medical Colleges have recommended that a one year internship be maintained. The essential character of the intern service has likewise been recognized by the Army, Navy and Selective Service, which have made provisions whereby medical students may be deferred from active military duty until they have completed a year of hospital training. It is necessary, however under present conditions that students eligible for military service begin their internship immediately on graduation. Those who are not subject to induction because of physical defects or other reasons are not officially restricted in length of internship, yet they should also complete their training as early as possible so as to be available for essential civilian needs.

In January 1942 608 of the approved hospitals were offering internships of twelve months' duration, 17 had services of eighteen months while 71 reported two year assignments. In addition there were 31 hospitals which had two services ranging from twelve to twenty-

four months and 5 other institutions in which the internship varied from twenty-one to thirty-six months. From reports received in January 1943 it is apparent that all of the intern hospitals are now offering a one year internship in accordance with military needs. Twenty-eight of these are also providing services of longer duration for such applicants as may be able to continue beyond the regular one year period. Ten of the longer assignments are eighteen months in length, while 18 are in the two year group.

INCREASED PRODUCTION OF INTERNS

It has been estimated that the accelerated program of medical education will produce over 21,000 medical graduates in the first three years of operation. Of this number approximately 9,560 will complete their undergraduate training in 1943. There is some variation in the dates of graduation of the medical schools and a careful study of these may permit some staggering of the dates of beginning of internships. However 4,180 medical graduates will be ready for intern service by the first of April, 681 by July 1, 255 by October 1 and 4,444 in the last three months of the year.

It is obvious that under present conditions there is no one solution to the problem of coordinating a twelve month internship with an incoming class of interns every nine months. Conditions vary in the intern hospitals, and a number of different programs have been adopted or are now under consideration. Some hospitals are experiencing such a shortage of interns that they will have little difficulty in accommodating a new group three months before the previous group has completed its year of service. Other institutions anticipating difficulty in providing quarters and satisfactory training schedules during the three months period of overlapping assignments are arranging for affiliated services in neighboring hospitals which are prepared to offer supplemental training acceptable to the hospital responsible for the internship. Only when an institution is prepared to assume supervision and responsibility for the affiliated three months training will it be in position to certify the completion of the required twelve months internship. Otherwise the hospital should issue certification for only such period of training as was actually under its own supervision. If a divided internship of nine and three months is served in two approved intern hospitals without a direct affiliation, the assignment in each hospital will be recorded separately in the biographic files of the American Medical Association. This is in accordance with the policy of the Council of listing educational services on the basis of institutional approval.

In some institutions the older interns will be assigned to senior positions carrying greater responsibility during the last three months of the internship. This method is especially applicable in hospitals which previously employed residents and assistant residents. A few hospitals are studying the possibility of assigning interns to senior staff physicians who would assume responsibility for their training during the final three months. Such preceptorships should be under the supervision of the hospital, however, and so correlated with the previous training that a well rounded internship will be provided.

The Surgeon General of the Army and the Surgeon General of the Navy have expressed their willingness to cooperate in every way possible and have indicated that as far as arrangements can be made and such a

procedure is desirable the facilities of the military hospitals will be made available for the completion of the last three months of the internship period. Many of the hospitals of the Army, the Navy and the United States Public Health Service are currently approved for intern training. The approved naval hospitals and those of the U. S. Public Health Service are also accepting interns for the full twelve months training program.

TYPES OF INTERNSHIPS

The Council on Medical Education and Hospitals approves rotating, mixed and straight internships. The most common is the rotating service which provides supervised experience in internal medicine, surgery, pediatrics, obstetrics and their related subspecialties together with experience in laboratory and radiologic diagnosis. The mixed internship is defined as one which provides supervised experience in two or more but not in all of the clinical divisions named. A straight internship is one which provides training in a single department, although it may include limited opportunity for work in a related subspecialty. Straight internships are now approved in internal medicine, surgery, pediatrics, obstetrics (with or without gynecology) and pathology.

In January 1942, 660 of the approved hospitals offered a full rotating service, 27 had mixed assignments, 18 had straight internships, 17 provided both rotating and straight service, 5 mixed and straight, 2 rotating and mixed, while 3 hospitals furnished all three types. At that time 86.1 per cent of the internship appointments were rotating in type, 3.4 per cent were mixed and 10.4 per cent straight.

Since the internship has long been considered an essential preparation for general practice and a prerequisite for subsequent specialty training, it is logical that most interns should prefer a rotating assignment to gain wide experience in relation to the various aspects of modern medicine. Military needs have also emphasized the importance of a general type of training during the initial hospital year. It is significant therefore, that the number of rotating internships has increased considerably in the last year. From current reports it is apparent that 635 hospitals exclusive of the federal hospitals approved for intern training are now offering a rotating service, 25 have mixed assignments and 16 provide straight internships. In addition there are 14 that have rotating and straight services, 4 rotating and mixed, 6 mixed and straight and 2 that provide all three types. According to these figures rotating internships are available in 93.3 per cent of the 702 hospitals included in this report. Of the individual internships available at present, 6,862, or 86.2 per cent, are rotating in type, 258, or 3.2 per cent, are mixed, while 839, or 10.5 per cent, are classified as straight.

NECROPSY PERFORMANCE

In 1942 the hospitals approved for intern training reported a total of 210,533 deaths exclusive of stillbirths and coroners' cases not available for teaching. The corresponding number of necropsies was 74,879 indicating an average necropsy rate of 35.6 per cent. While there has been some reduction in the number of necropsies since last year, it should be noted that these figures do not include the federal hospitals approved for intern training, which ordinarily have a high ratio of necropsy performance. From 1938 to 1941 the average necropsy rates were 37.6, 37.8, 38.9 and 38.97 per cent respec-

tively. Table C gives comparative data for several annual periods since 1926. In this the most striking feature perhaps is the rapid response of the approved hospitals to the requirement of the Council that a minimum rate of at least 15 per cent be maintained after Jan. 1, 1929. There has likewise been a notable increase in the higher percentage groups showing that the hospitals are constantly striving to improve their educational facilities. In the last year, however, the loss of medical personnel incident to military needs has apparently affected the ability of several hospitals to maintain their usual level of necropsy performance. Forty-three fell below the minimum requirement of 15 per cent as compared with 18 in 1941. The fact that 116 hospitals had necropsy rates above 50 per cent is indeed encouraging, for it illustrates clearly that even under conditions imposed by war it is possible to maintain efficiently the essential functions of an educational program. Twenty-one hospitals had the highly commendable rate of 70 per cent or over, as shown in the accompanying list. Their achievement should serve to stimulate other hospitals to greater effort in relation to educational needs. Under present conditions it is especially important that the medical and administrative personnel concerned with the training of house

TABLE C—Necropsy Performance in Approved Intern Hospitals

* Does not include federal hospitals approved for intern training.

officers exert every effort to insure their adequate preparation for civilian and military service.

The intern and residency hospitals combined had an average necropsy rate of 35.2 per cent on the basis of 249,383 deaths and 87,687 postmortem examinations. The other registered hospitals not approved for internships or residencies reported 252,951 deaths in 1942 and 28,616 necropsies—a ratio of 11.3 per cent. The amount of necropsy material available for teaching purposes in the approved hospitals is shown in table D.

RESIDENCIES AND FELLOWSHIPS

Of the 6,345 hospitals registered by the American Medical Association 646 are currently approved for the training of resident physicians, not counting six federal hospitals which also hold residency approval. Included in this group are 310 of the 702 hospitals reported as having approved internship programs. From reports received in January 1943 it is apparent that the 646 residency hospitals are offering 5,596 residencies, assistant residencies and fellowships as shown in table E. At the time of reporting only 4,082 of these positions were filled, however, indicating a shortage of 1,514 in comparison with the number desired.

For further information regarding the present status of residencies in relation to hospital and military needs, reference should be made to the article Medical Education and the Procurement and Assignment Service by

H S Diehl, M D, member, Directing Board, Procurement and Assignment Service, published in THE JOURNAL, Feb 27, 1943, p 635. This article indicates that in general the number of hospital residents should be less than 50 per cent of the number employed before the war and that this figure must be reduced still more in 1943. Residencies and fellowships, therefore, should be limited to such assignments as are essential for the provision of adequate medical care for hospital patients and for the clinical training of medical students. When vacancies exist it has been recommended that essential residencies be filled by the following groups in order: (1) women physicians, (2) men physicians who are physically disqualified for military service, (3) other interns or residents deferred by Selective Service, (4) qualified graduates of foreign medical schools.

The approval of residencies by the Council began in 1927, when 278 hospitals were certified for advanced training. Prior to that time the special hospital assignments were included in the approved intern list, which was first published in 1914. From 1927 to 1942 the opportunities for residency training have practically tripled in number in view of the increase of available positions from 1,776 to 5,293 and the number of approved hospitals from 278 to 632. In recent years there has been considerable acceleration in the growth of residencies because of the development of the certifying boards and the continuing emphasis on specialization. For the duration of the war, however, a curtailment of graduate training must necessarily take place.

reappraisal of services previously approved. Consideration is now being given to postwar needs, for it is apparent that large numbers of physicians may wish to resume their graduate training or begin new hospital assignments as soon as their military duties have been completed. To help meet this demand the Council is planning to make a survey of all potential and available facilities for graduate training in connection with hospitals, undergraduate and graduate medical schools, clinics, departments of health and other agencies interested in graduate or postgraduate education. No doubt there will be opportunities for the development of additional high grade training programs in institutions that have not yet reached their full educational capacity. The Council is confident that all institutions and agencies concerned will give every assistance in connection with this survey.

to meet the needs of the armed forces. In many instances there will be opportunities for continued specialty training in army and naval hospitals for which credit may be assigned in accordance with the regulations issued by the individual certifying boards. Reference should be made to the Educational Number of THE JOURNAL, Aug 15, 1942, page 1345.

In January 1942 the 1,070 hospitals approved for internships and/or residencies employed 7,219 interns, 3,311 residents, 2,036 assistant residents and 802 fellows. At present 1,038 approved hospitals have 5,567

* Number of hospitals approved for residencies and fellowships 610

interns on duty, 2,633 residents, 1,210 assistant residents and 609 fellows. These hospitals reported 5,804,279 admissions in 1942, an average daily census of 423,246, and 23,644,700 outpatient visits. Reference should be made to table F, showing the number of available positions as well as the number of house officers now serving. In comparing these figures with table E it is apparent that 370 members of the resident staff are employed in departments that have not yet been approved for residency training. Detailed information concerning individual residencies on the approved list is published annually in the Educational Number of THE JOURNAL.

DISEASE NOMENCLATURE

In 1938 the Council on Medical Education and Hospitals included in its questionnaire addressed to hospitals an inquiry asking for the disease nomenclature used by them. Of those which replied at that time, 753 stated that they were using the Standard Classified Nomenclature of Disease and 1,063 stated that they were using either the Bellevue Hospital, Ponton Alphabetical or the Massachusetts General Hospital, and 1,067 reported the use of other classifications or none at all. This question was repeated in slightly different form in the questionnaire sent to hospitals in 1942. Of those which replied, 1,014 stated that they were using

the Standard Nomenclature of Disease. Ninety-one institutions reported using the classification of the American Psychiatric Association, which is identical with the psychiatric section in the Standard Nomenclature of Disease. The Ponton Alphabetical Nomenclature, the Bellevue Hospital or the Massachusetts General Hospital classifications were reported in use by 1,079 hospitals. A total of 616 hospitals employ other nomenclatures, most of which have not been designed for modern use. The remaining institutions did not reply to this question and were evidently unfamiliar with the need and purposes of disease nomenclature.

It would be desirable that hospitals planning to establish a disease classification or reorganize their present

system should consider the adoption of a nomenclature that is suitable for universal use. The Standard Nomenclature of Disease has been officially endorsed by the American Medical Association, the American College of Surgeons, the American Hospital Association and several other medical and surgical societies.

HOSPITALS REGISTERED BY THE AMERICAN MEDICAL ASSOCIATION

The following list contains the names of 6,345 hospitals, sanatoriums and related institutions that are located in the United States and 128 in Alaska, Canal Zone, Hawaii, Puerto Rico and Virgin Islands. The list for each state is presented in two groups: (1) hospitals and sanatoriums, and (2) related institutions. The related institutions include infirmaries, nursing homes and other institutions designed to give certain medical and nursing care in an ethical and acceptable manner, without giving a full hospital service.

Registration of hospitals is governed by the Essentials of a Registered Hospital, adopted by the House of Delegates in 1928 and revised in 1939.

Registration is a basic recognition, extended to all the hospitals and related institutions in the following list, concerning which we have no evidence of irregular or unsafe practices. Approval is designation of certain registered institutions by the Council on Medical Education and Hospitals for internships, residencies and fellowships, or by the American College of Surgeons as unconditionally meeting its minimum standards.

KEY TO SYMBOLS AND ABBREVIATIONS

* Approved for training interns by the Council on Medical Education and Hospitals. List with detailed information is sent on request.
+ Approved for residencies or fellowships. List with detailed information is sent on request.

▲ Approved by American College of Surgeons as meeting unconditionally its minimum standards.
◊ School of nursing accredited by state board of nurse examiners.
○ Affiliated for nurse training on state accredited basis.
† Figures for average census and admissions are exclusive of newborn infants.

The column headed "Type of Service" tells what diseases are treated in each institution.

Card	Cardiac	ENT	Eye, ear, nose and throat	Is	Isolation	NM	Nervous and mental
Chil	Children	Gen	General	Mat	Maternity	Orth	Orthopedic
Chr	Chronic	Incur	Incurable	MatCh	Maternity and children	SkCa	Skin and cancer
Conv	Convalescent and rest	Indus	Industrial	MeDe	Mentally deficient	TB	Tuberculosis
Drug	Drug and alcoholic	Inst	Institutional	Ment	Mental	Ven	Veneral
Fphl	Epileptic						

The column headed "Control" indicates control, or auspices under which the institution is conducted.

GOVERNMENTAL				NONPROFIT ORGANIZATIONS		PROPRIETARY	
Fed	Federal	State		Church		Indiv	Individual
IA	Indian Affairs	City		NPA	Nonprofit Association	Part	Partnership
Army	United States Army	County				Corp	Corporation (unrestricted as to profit)
Navy	United States Navy	City/County					
USPHS	United States Public Health Service	CyCo					
Vet	Veterans Administration Facility						

The accompanying list omits additions to hospital facilities that may have been made by certain departments of the Federal Government since the publication of the issue of March 15, 1941.

Corrections were made in the list to the time of going to press. Totals of the list, therefore, may vary from totals in Tables 1 and 2 which were necessarily compiled earlier.
